## Acknowledgements

The *Preparing for Life* Team and the UCD Geary Institute would like to thank all those who participated in and supported this research.

This research could not happen without the co-operation of the parents/families who agreed to participate and the junior infant teachers who acted as the link with the families. We would like to acknowledge the principals and boards of management of the three schools Our Lady Immaculate, Darndale, St. Francis, Priorswood and St. Joseph's, Bonnybrook for supporting the project. We also sincerely thank the parents and junior infant teachers for the time they took to complete the survey questionnaires.

*Preparing for Life* would particularly like to thank the UCD Geary Institute Team (Ailbhe Booth, Catherine O'Melia, Edel McGlanaghy, Eyllin Palamaro Munsell and Peter Carney) under the direction of Dr. Orla Doyle, for their work in analysing the data gathered and writing up this report. We also thank Victoria Monkhouse for her role in liaising between the schools and the research team. Dr. Orla Doyle would also like to thank the Offord Centre for Child Studies, McMaster University for providing their assistance in coding the data obtained.

We also again thank our funders The Atlantic Philanthropies and the Department of Children and Youth Affairs for their on-going support of *Preparing for Life* and acknowledge the advice and guidance given by staff of both organisations. We thank the Northside Partnership and *Preparing for Life* boards for their on-going support. We also thank our Expert Advisory Committee for their technical support and guidance.

Finally we are most grateful to the St. Stephen's Green Trust for provided the funding to publish this report.

Noel Kelly,

Manager, *Preparing for Life*

## Executive Summary

The Children's Profile at School Entry (CPSE) was conducted by the UCD Geary Institute who are commissioned by the Northside Partnership to assess the levels of school readiness in several designated disadvantaged communities of Ireland, as part of an overall evaluation of the *Preparing for Life (PFL)* early childhood intervention programme.

### **Purpose and Description of the CPSE**

The CPSE is an annual representative survey of the levels of school readiness of Junior Infant children attending the local primary schools in the *PFL* catchment area. These surveys 1) indicate the general level of school readiness of children attending schools in the *PFL* catchment area, 2) indicate whether the *PFL* programme is generating positive externalities, and 3) serve as a baseline measure of school readiness for the *PFL* cohort.

### **CPSE Methodology**

The CPSE is conducted between October and December of each year starting in 2008 and continuing through 2013. Five waves of data have been collected to date. Data were collected via online questionnaires completed by teachers and paper and pen questionnaires completed by caregivers. The teachers' and caregivers' response rates were 99% and 76% (Wave 1), 98% and 78% (Wave 2), 100% and 81% (Wave 3), 100% and 81% (Wave 4) and 99 % and 82% (Wave 5) respectively, resulting in a total CPSE cohort of 565 children. Thus, the response rates are high and have been improving over time.

Pupil school readiness was assessed using teacher and caregiver reports on the Short Early Development Instrument (S-EDI; Janus, Duku, & Stat, 2005). The S-EDI is composed of 48 core items and provides scores across five domains of school readiness: *physical health and well-being*, *social competence*, *emotional maturity*, *language and cognitive development*, and *communication and general knowledge*. The S-EDI has normative data that correspond to each domain, allowing comparisons with a representative Canadian sample.

## **Results**

### **School Readiness in the Wave 1 (2008-2009) CPSE Cohort**

- Teachers rated children in the CPSE Wave 1 cohort as displaying significantly *lower* levels of school readiness than a Canadian norm, while caregivers rated children as displaying significantly *higher* levels of school readiness than a Canadian norm.
- Children were rated highest on *physical health and well-being* and *social competence*, while they were rated lowest on the *communication and general knowledge* domain by teachers and were rated lowest on the *language and cognitive development* domain by caregivers.
- Approximately 50% of children in the CPSE Wave 1 cohort were performing *above* the Canadian norm in terms of *physical health and well-being* and *social competence*. Approximately 70% of children were rated *below* the norm on the *emotional maturity*, *language and cognitive development*, and *communication and general knowledge* domains, demonstrating specific areas of weakness for a large portion of the CPSE Wave 1 cohort.
- Just fewer than 18% of children scored in the lowest 10% of the entire CPSE cohort on one of the five S-EDI domains and a further 10% scored low on two domains, with 9% scoring low on three or more domains.

### **School Readiness in the Wave 2 (2009-2010) CPSE Cohort**

- Teachers rated children in the CPSE Wave 2 cohort as displaying significantly *lower* levels of school readiness than a Canadian norm, while caregivers rated children as displaying significantly *higher* levels of school readiness than a Canadian norm.
- Children were rated highest on *physical health and well-being* and *social competence* and lowest on the *language and cognitive development* domain by both teachers and caregivers.
- Approximately 60% of children in Wave 2 of the CPSE cohort were performing *above* the norm in terms of *social competence*. Approximately 55% to 60% of children were rated *below* the Canadian norm on the *physical health and well-being*, *emotional maturity*, and *communication and general knowledge* domains. Seventy-four percent of children in Wave 2 were rated *below* the norm on the *language and cognitive development* domain, demonstrating specific areas of weakness for a large portion of the CPSE Wave 2 cohort.
- About 12% of children in Wave 2 scored in the lowest 10% of the cohort on one of the five S-EDI domains, a further 4% scored low on two domains, and less than 7% scored low on three or more domains.

### **School Readiness in the Wave 3 (2010-2011) CPSE Cohort**

- Teachers rated children in the CPSE Wave 3 cohort as displaying significantly *lower* levels of school readiness than a Canadian norm, while caregivers rated children as displaying significantly *higher* levels of school readiness than a Canadian norm on the *physical health and well-being*, *social competence*, and *communication and general knowledge* domains. However, caregivers rated children significantly *lower* than the Canadian norm on the domains of *emotional maturity* and *language and cognitive development*, representing a change from previous years.
- Children were rated highest on the *physical health and well-being* domain by both teachers and caregivers, while they were rated lowest on the *communication and general knowledge* domain by teachers and were rated lowest on the *language and cognitive development* domain by caregivers.
- Fifty percent of children in the CPSE Wave 3 cohort were performing *above* the Canadian norm in terms of *social competence*, approximately 40% of children were rated *above* the norm on the *physical health and well-being* and *emotional maturity* domains, while 70% were rated *below* the Canadian norm on the *language and cognitive development* and *communication and general knowledge* domains. Together with the results from Waves 1 and 2, these findings identified certain areas of weakness for a large number of children attending schools in the PFL catchment area.
- Approximately 15% of children scored in the lowest 10% of the entire CPSE cohort on one of the five S-EDI domains and a further 4% scored low on two domains, with 5% scoring low on three or more domains of school readiness.

### **School Readiness in the Wave 4 (2011-2012) CPSE Cohort**

- Teachers rated children in the CPSE Wave 4 cohort as displaying significantly *lower* levels of school readiness than a Canadian norm on the *physical health and well-being*, *emotional maturity*, *language and cognitive development* and *communication and general knowledge* domains, while caregivers rated children as displaying significantly *higher* levels of school readiness than a Canadian norm on the *physical health and well-being*, *social competence*, *emotional maturity* and *communication and general knowledge* domains. However, similar to Wave 3, caregivers rated

children significantly *lower* than the Canadian norm on the *language and cognitive development* domain.

- Children were rated highest on the *social competence* domain by teachers and on the *physical health and well-being* domain by caregivers, while they were rated lowest on the *language and cognitive development* domain by both teachers and caregivers.
- Sixty percent of children in the CPSE Wave 4 cohort were performing *above* the Canadian norm in terms of *social competence*, approximately 43-46% of children were rated *above* the norm on the *physical health and well-being*, *emotional maturity* and *communication and general knowledge* domains, while 70% were rated *below* the Canadian norm on the *language and cognitive development* domain. Together with the results from Waves 1, 2 and 3 these findings identified certain areas of weakness for a large number of children attending schools in the PFL catchment area.
- Approximately 12% of children scored in the lowest 10% of the entire CPSE cohort on one of the five S-EDI domains and a further 11% scored low on two domains, with 6% scoring low on three or more domains of school readiness.

### **School Readiness in the Wave 5 (2012-2013) CPSE Cohort**

- Teachers rated children in the CPSE Wave 5 cohort as displaying significantly *lower* levels of school readiness than a Canadian norm on *all domains* of school readiness, while caregivers rated children as displaying significantly *higher* levels of school readiness than a Canadian norm on the *physical health and well-being*, *social competence*, *emotional maturity* and *communication and general knowledge* domains. However, similar to Waves 3 and 4, caregivers rated children significantly *lower* than the Canadian norm on the *language and cognitive development* domain.
- Children were rated highest on the *physical health and well-being* domain by both teachers and caregivers, while they were rated lowest on the *language and cognitive development* domain by both teachers and caregivers.
- Fifty-five percent of children in the CPSE Wave 5 cohort were performing *above* the Canadian norm in terms of *social competence*, approximately 35-47% of children were rated *above* the norm on the *physical health and well-being*, *emotional maturity* and *communication and general knowledge* domains, while 80% were rated *below* the Canadian norm on the *language and cognitive development* domain. Together with the results from previous waves these findings identified certain areas of weakness for a large number of children attending schools in the PFL catchment area.
- Approximately 18% of children scored in the lowest 10% of the entire CPSE cohort on one of the five S-EDI domains and a further 4.5% scored low on two domains, with 11% scoring low on three or more domains of school readiness.

### **Differences in School Readiness between the Cohorts**

Figures 1 and 2 illustrate no clear similarities in the patterns of mean scores across the five waves of data. According to teacher reports, children in Waves 2, 3 and 5 were rated as displaying significantly higher levels of *emotional maturity* than children in Wave 1. However, according to caregiver reports, children in Waves 1, 2, 4 and 5 were rated as displaying significantly more *emotional maturity* than children in Wave 3. Caregivers rated children in Wave 1 significantly higher in the *language and cognitive development* domain than children in Wave 3. Teachers rated children significantly higher in the *social competence* domain in Wave 4 than children in Waves 1, 3 and 5. While this suggests some differences in school

readiness skills between the cohorts, we cannot conclude that this is a result of externalities from the *PFL* programme as it also may be driven by differences in teacher and caregiver reporting or cohort effects.

*Figure ES1.* Between wave differences on teacher rated S-EDI school readiness domains. Error bars represent the standard error of the mean and can be used to visually evaluate differences between two means. Specifically, if the error bars for two means do not overlap, it is a good indication that these two means are statistically different from each other.

*Figure ES2.* Between wave differences on caregiver rated S-EDI school readiness domains. Error bars represent the standard error of the mean and can be used to visually evaluate differences between two means. Specifically, if the error bars for two means do not overlap, it is a good indication that these two means are statistically different from each other.

### **Importance of School Readiness Domains**

Examining the importance placed on the five school readiness domains revealed differences in teacher and caregiver perceptions. Specifically, the largest percentage of teachers (36%) indicated that emotional maturity was the *most important* domain for school readiness and 40% of teachers indicated that *physical health and well-being* was the *least important* domain for a child's school readiness. Caregiver ratings, on the other hand, showed a distinctly different pattern. The largest percentage of caregivers (42%) rated the *physical health and well-being* domain as *most important* for a child's school readiness and 35% of caregivers rated the *language and cognitive development* domain to be the *least important* developmental area. This divergence in teacher and caregiver values may represent differential capabilities that are focused on in the home and in the school environment. Exposure to diverging messages about the skills which are important for school success may adversely affect children's school readiness.

### **Subjective School Readiness**

Teachers in Waves 2, 3, 4 and 5 of the CPSE cohort indicated that approximately 50% of children were *definitely ready* for school when they started in September. This is consistent with teacher ratings in the 2004-2005 cohort (Kiernan et al., 2008), suggesting that there have been few improvements in children's school readiness, as reported by teachers, in the *PFL* communities over an eight year period.

### **Group Differences in School Readiness**

The report also investigated differences in school readiness scores across a range of socio-demographic, health, and environmental factors. For these analyses, data from all waves were combined. Teacher rated differences reported here are significant at the 5% level or below.

- Older children were rated as being more *physically healthy*, were more *socially competent*, and displayed higher levels of *communication and general knowledge*.
- Girls were reported to have greater *physical health and well-being*, to be more *socially competent*, more *emotionally mature*, have better *language and cognitive development* and to display higher levels of *communication and general knowledge* than boys.
- Children with no siblings were rated as being more *physically healthy* and *socially competent*, have better *language and cognitive development* and to display higher levels of *communication and general knowledge* compared to children with at least one sibling. Additionally, the number of siblings was found to be negatively associated with *all five* domains of school readiness.
- Children of caregivers with relatively higher levels of education were rated higher on *all five* domains of school readiness than children of caregivers with lower education levels.
- Children of caregivers in paid work were rated higher on *all five* domains of school readiness than children living in households where the caregiver was not in paid work.
- Children of caregivers not in receipt of social welfare payments were rated as being more *physically healthy*, *socially competent* and *emotionally mature*, as well as displaying higher levels of *language and cognitive development* than children of caregivers in receipt of social welfare payments.
- Children of caregivers who reported low levels of depressive symptomology displayed higher levels of *social competence* than children of caregivers who reported high levels of depressive symptomology.

- Differences in school readiness scores based on caregivers' relationship status, age, mental well-being and self-rated health did not reach significance.
- The majority of children (81%) in the cohort had experienced some form of centre-based childcare prior to school entry. Children who spent any amount of time in centre-based childcare prior to school entry were rated higher than children who did not experience any centre-based childcare in the domains of *language and cognitive development and communication and general knowledge*. Additionally, longer duration in centre-based childcare was associated with higher ratings in *language and cognitive development and communication and general knowledge*.

### **Factors Associated with School Readiness**

A multivariate analysis was conducted with the combined cohort data from Waves 1 to 5 to assess the impact of multiple factors relevant to school readiness. None of the factors were associated with all domains of school readiness. However, several unique relationships were identified. Specifically, being an older child was associated with an increase in *social competence* ratings. Female children displayed higher levels of *social competence, emotional maturity, and communication and general knowledge*. Children of caregivers with higher levels of education showed higher levels of *language and cognitive development*, and children of caregivers in paid work evidenced higher levels of *communication and general knowledge*, while holding all other variables constant. Finally, children of caregivers who are in receipt of social welfare payments displayed lower levels of *social competence and emotional maturity*.

### **Parenting Behaviours and School Readiness**

Several significant relationships between authoritative, authoritarian and permissive parenting behaviours and teacher reported school readiness were present in the CPSE cohort.

- Authoritative parenting was not associated with any of the domains of school readiness.
- Authoritarian parenting was negatively associated with *overall social competence with peers and responsibility and respect*.
- Permissive parenting was negatively associated with *basic literacy skills and social competence* specifically, *responsibility and respect and approaches to learning*; and positively associated with *aggressive behaviour and anxious and fearful behaviour*.

### **Conclusion**

Based on teacher assessments of school readiness, the children in the *PFL* catchment area were not performing to the level of other similar aged children at school entry, a finding that provides quantitative evidence of the need for the *PFL* intervention. However, there is much heterogeneity within the cohort, with sub-groups of children performing above the Canadian norm. There is some evidence suggesting that the Wave 4 cohort were performing above the Wave 1, 2, 3 and 5 cohorts in terms of teacher rated social competence. There also is evidence signifying that the Wave 2, 3, 4 and 5 cohorts were performing above the Wave 1 cohort in terms of *emotional maturity*, however, overall the same pattern of results emerged between waves. Combining the data from all five waves allowed for better investigation of the factors associated with school readiness. Being a male child and having a parent in receipt of social welfare was negatively associated with multiple domains of school readiness. The report will be amended annually until 2015 to include the results of each consecutive data collection wave, in addition to comparisons examining annual changes in levels of school readiness. Finally, please note that the CPSE survey was conducted with a sample of Junior Infant children living in a disadvantaged urban area of Ireland, therefore these results should not be generalised to the wider population.

## Introduction

### A. Background & Aims

The Children's Profile at School Entry (CPSE) was conducted by the UCD Geary Institute who have been commissioned by Northside Partnership to assess the levels of school readiness in several designated disadvantaged communities of Ireland as part of an overall evaluation of the *Preparing for Life (PFL)* early childhood intervention programme.

In 2004, a school readiness survey was conducted by the Children's Research Centre in Trinity College Dublin (Kiernan et al., 2008) in the *PFL* catchment area. In this survey, teachers reported that only 48% of children were *definitely ready* for school. As a result, the *PFL* programme was developed with the aim of increasing the levels of school readiness in these disadvantaged areas.

*PFL* is a five year school readiness intervention starting in pregnancy and lasting until the children start school. The programme is jointly funded by The Atlantic Philanthropies and the Department of Children and Youth Affairs. The aim of the programme is to work with families from pregnancy onwards to help and support the healthy development of the child. All programme families receive facilitated access to enhanced preschool and public health information, as well as the services of a support worker. In addition, half of these families are randomly allocated to receive enhanced supports including participation in a home-visiting mentoring programme and a group parent training programme. This experimental programme is one of the first of its kind in Ireland and aims to provide real time evidence on best practice in early intervention.

The CPSE is an annual representative survey of the levels of school readiness of Junior Infant children attending the local primary schools in the *PFL* catchment area. Specifically, the survey focuses on the children's levels of school readiness in the year they start school, and:

- 1) Indicates the general level of school readiness of children in the *PFL* catchment area.

- 2) Indicates whether the *PFL* programme is generating positive externalities (i.e., whether the public health style messages and improved service integration by the local providers translate into improved levels of school readiness).
- 3) Serves as a baseline measure of school readiness for the *PFL* cohort.

## **B. Overview of Report**

This report describes the results from the first five years of the annual CPSE survey. The report will be amended annually until 2015 to include the results of each consecutive data collection wave. In addition to comparing annual changes in levels of school readiness, the report also examines relationships between teacher reported school readiness and socio-demographic, health, and environmental factors of the families and children participating in the study. The report is organised as follows:

- Sections C - D provide a brief description of school readiness.
- Sections F – H discuss the methodology employed.
- Sections J – P present the results of the analysis.
- Sections Q - EE summarise and conclude the report.

What is School Readiness?

## **C. Definition of School Readiness**

School readiness is a multi-dimensional concept which reflects the holistic nature of children's development and takes account of a host of factors in their wider environment. While the traditional definition of school readiness focused on academic ability alone, more recent research on child development and early education has noted that school readiness is a multi-faceted concept which also includes physical health and well-being, motor development, social and emotional development, approaches to learning, language development, and emergent literacy (Child Trends, 2001; Kagan, Moore, & Bradenkamp, 1995). Together, these developmental domains have the capacity to influence the child's readiness for school and future academic achievement, as children who begin school with the appropriate cognitive and social skills maintain this advantage throughout the school years.

## **D. Determinants of School Readiness**

International research has identified several factors that influence a child's readiness for school. Key factors include child health, family factors, emergent literacy practices, early childhood care and education, school transitional practices, as well as community, neighbourhood, and media effects (Halle, Zaff, Calkins, & Geyelin-Margie, 2000).

## **E. Importance of School Readiness**

School readiness is important across a wide range of developmental areas as each dimension of school readiness may have consequences for a child's social, physical, and educational outcomes. In particular, developmental problems in childhood are associated with negative life outcomes in adulthood. Poor school readiness has been linked to later academic failure (Raver, 2003), poor socio-emotional adjustment (Arnold et al., 1999; Hinshaw, 1992), and poor life outcomes such as unemployment (Ross & Shillington, 1990) and teenage pregnancy (Brooks-Gunn, 2003). School readiness has been described as a foundation on which all later learning is built and it has been argued that children who develop well at earlier stages and are ready to start school are in a position to elicit interactions and experiences that accelerate their subsequent development and facilitate their achievement (Heckman, 2000).

For a complete review of the definition, determinants, and importance of school readiness please refer to the full report from the first year of the CPSE project (2008-2009) located on the *PFL* Evaluation website (<http://geary.ucd.ie/preparingforlife/>).

## Methodology

### **F. Participants**

#### ***1. Survey Design and Piloting***

In order to assess the level of school readiness in the *PFL* catchment area, a cross-sectional design was developed which collects information via surveys completed by the teachers and primary caregivers of Junior Infant children living in the area. Data were collected annually beginning in the 2008-2009 school year.

**Wave 1:** Data for Wave 1 of the CPSE were collected during October, November, and December of the 2008-2009 academic year. All survey instruments were piloted prior to administering the surveys to the study population.

**Wave 2:** Data for Wave 2 of the CPSE were collected during October, November, and December of the 2009-2010 academic year. A few additions were made to the Wave 2 survey. Specifically, questions assessing the caregivers' mental well-being, subjective perceptions of general health, and teacher and caregiver perceptions of the Junior Infant child's school readiness when he/she began school in September of that academic year, were added to the questionnaire.

**Wave 3:** Data for Wave 3 of the CPSE were collected during October, November, and December of the 2010-2011 academic year. Two additions were made to the Wave 3 survey. Specifically, questions assessing the caregivers' depressive symptoms were added and secondly, teachers and caregivers were asked to identify the area of development they perceived to be most and least important for a child's school readiness.

**Wave 4:** Data for Wave 4 of the CPSE were collected during October, November, and December of the 2011-2012 academic year. No additional changes were made to the Wave 4 survey.

**Wave 5:** Data for Wave 5 of the CPSE were collected during October, November and December of the 2012-2013 academic year. A few additions were made to the Wave 5 primary carer survey. Specifically, questions were included regarding the date on which the questionnaire was completed and which preschool/crèche the children had attended. In addition, the questions relating to household composition were modified to increase the accuracy of the caregiver response.

#### **a) Teacher Questionnaire**

The teacher questionnaire was administered using an online survey in which the teachers accessed a secure website using a unique user ID and password. The questionnaire took approximately 10 minutes to complete for each child. Teachers were asked a number of

demographic questions, as well as questions regarding the school readiness of participating children.

### **b) Caregiver Questionnaire**

Caregivers were recruited via their child's teacher. The paper and pen questionnaire took approximately 30 minutes for the caregiver to complete. The questionnaire consisted of questions regarding socio-demographic and household information, caregiver health and well-being, child school readiness, and parenting behaviour. Although the vast majority of respondents for all waves (88%) were the biological mother of the CPSE children, three grandmothers and ten biological fathers also completed the caregiver questionnaire. For these cases, the Junior Infant child resided in the same house as the respondent, therefore it was assumed that the respondent played a primary caregiving role for the child and was knowledgeable about the child's behaviours. Thus, these data were retained.

## ***2. Eligibility***

**Wave 1:** All teachers and caregivers of Junior Infant children either residing in or attending schools in the original *PFL* catchment area were eligible for participation in the study. This resulted in two eligible primary schools. Primary caregivers of children who did not reside in the area themselves, but their children attended schools in the catchment area, also were asked to participate to ensure no child was excluded or singled out in the classroom. Finally, children who lived in the *PFL* catchment area, but attended schools outside the area ( $n=21$  from five schools) also were invited to participate. Caregivers gave consent to complete the questionnaire themselves and also for their child's teacher to complete the questionnaire about their child's behaviour.

**Wave 2:** All teachers and caregivers of Junior Infant children attending schools in the original and the extended *PFL* catchment area were eligible for participation in the study. The *PFL* catchment area was expanded in January, 2009 and again in June, 2009. Therefore, the enlarged catchment area comprised three eligible primary schools. Primary caregivers gave consent to complete the questionnaire themselves and also for their child's teacher to complete the questionnaire. As in Wave 1, caregivers of children who did not reside in the area themselves, but were attending schools in the area, also were asked to participate.

**Wave 3, Wave 4 and Wave 5:** All teachers and caregivers of Junior Infant children attending the three primary schools in the original and the extended *PFL* catchment area were eligible for participation in the study. Note that these are the same three schools represented in Wave 2. Primary caregivers gave consent to complete the questionnaire themselves and also for their child's teacher to complete the questionnaire. As in Waves 1 and 2, caregivers of children who did not reside in the area themselves, but were attending schools in the area, also were asked to participate.

### ***3. Response Rates***

**Wave 1:** There were a total of 123 eligible pupils across five schools. In total, 94 caregiver questionnaires were returned resulting in a response rate of 76%. In total, 101 teacher questionnaires were completed, capturing data for 82% of eligible participants. Teacher questionnaires were completed for all pupils with consent, bar one, resulting in a teacher response rate of 99%.

**Wave 2:** There were a total of 165 eligible students across three schools. In total, 129 caregiver questionnaires were returned resulting in a response rate of 78%. Of these, 126 (76%) caregivers gave consent for the teacher to complete the survey regarding their child and 123 of these teacher questionnaires were completed, resulting in a teacher response rate of 98%, capturing teacher data for 75% of eligible children.

**Wave 3:** There were a total of 131 eligible students across three schools. In total, 106 caregiver questionnaires were returned resulting in a response rate of 81%. In addition, 110 (84%) caregivers gave consent for the teacher to complete the survey regarding their child and 110 of these teacher questionnaires were completed, resulting in a teacher response rate of 100%, capturing teacher data for 84% of eligible children.

**Wave 4:** There were a total of 130 eligible students across three schools. In total, 105 caregiver questionnaires were returned resulting in a response rate of 81%. Of the 130 eligible students,

106 parents gave consent for the teacher to complete the survey regarding their child and 106 (100%) of these questionnaires were completed.

**Wave 5:** There were a total of 135 eligible students across three schools. In total, 111 caregiver questionnaires were returned resulting in a response rate of 82%. Of the 135 eligible students, 112 parents gave consent for the teacher to complete the survey regarding their child and 111 (99%) of these questionnaires were completed.

#### ***4. Participation in the PFL Programme***

One of the goals of the annual CPSE survey is to indicate whether the *PFL* programme is generating positive externalities, that is, whether the benefits of participating in the *PFL* programme are passed on to older siblings in the family, resulting in improved school readiness. Thus, it is first important to determine whether families participating in the CPSE survey also are participating in the *PFL* programme. Although the number of families participating in both the CPSE survey and the *PFL* programme has increased throughout each wave of data collection, the number remains small. Specifically, two families (2.41%) in Wave 1 were participating in the *PFL* programme, four (3.28%) in Wave 2, eight (8.08%) in Wave 3, 15 (15.15%) in Wave 4 and 17 (15.7%) families in Wave 5 were participating in the *PFL* programme at the time of CPSE data collection. It is expected that this number will increase in the coming years as the *PFL* cohort start school. For example, it is anticipated that 61 children enrolled in the *PFL* programme will be eligible to enter Junior Infants in September, 2013, with numbers increasing to 90 in September, 2014, and the final 31 children enrolled in the *PFL* programme will be eligible to enter Junior Infants in September, 2015.

### **G. Instruments**

#### ***1. Teacher Demographics***

Teachers were asked a number of demographic questions including their age, professional qualifications, how long they had been teaching in general, how long they had been teaching at their current school, and how long they had taught Junior Infant classes.

## **2. Household Demographics**

Caregivers were asked socio-demographic information related to family composition, respondent age, ethnicity, employment and education, family income, social welfare status, and childcare utilisation.

## **3. Caregiver Health**

Mental well-being was assessed using the five item WHO-5 (World Health Organisation, 1998) instrument, a measure of positive mental health.

The Center for Epidemiologic Studies Depression Scale (CES-D; Radloff, 1977) was used, beginning in Wave 3, to measure caregiver self-reported depressive symptomology. The CES-D comprises 20 items assessing various depressive symptoms such as depressed mood, feelings of guilt, feelings of hopelessness, loss of appetite, and sleep disruptions.

The subjective health of caregivers was assessed via the question: ‘*In general, how would you describe your overall, general health?*’ Caregivers were asked to indicate if they would describe their health as *excellent, very good, good, fair, or poor*. Responses to this question range from one to five with higher scores representative of better self-reported health.

## **4. Parenting**

Parenting was assessed using the Parenting Styles and Dimensions Questionnaire (PSDQ; Robinson, Mandlco, Olsen, & Hart, 2001). This 32-item self-report measure of parenting examines how often the caregiver displays certain behaviours toward his/her child and yields scores related to the traditional Baumrind (1966; 1967; 1971) parenting styles. Caregivers were asked to indicate how often they performed certain behaviours on a five point scale ranging from *never* to *always*. This measure provided scores on three domains regarding caregivers’ average use of authoritative parenting, authoritarian parenting, and permissive parenting behaviours. The *authoritative* domain is composed of items related to connection, regulation, and autonomy. The *authoritarian* domain comprises items assessing physical coercion, verbal hostility, and non-reasoning/punitive behaviours. Lastly, the *permissive* domain contains items such as ‘*states punishments to child and does not actually do them,*’ and ‘*spoils child.*’ Examples of these items are presented in Table 1 of Appendix A.

## 5. *School Readiness*

The core measure of school readiness in the CPSE survey is a short form of the Early Development Instrument (EDI; Janus & Offord, 2000), which was developed at the Offord Centre of Child Studies (OCCS), McMaster University (Hamilton, Ontario, Canada). It was developed to meet the needs implied by the paradigm shift in school readiness research in which a more holistic definition of school readiness was adopted. The OCCS has established normative data for the EDI which sets a representative benchmark for comparison of data from projects using the instrument. Research comparing the predictive capability of the EDI with direct assessments of school readiness has shown that the EDI predicts school achievement in early childhood as accurately as direct assessments of school readiness (Fantuzzo, Bulotsky-Shearer, Fusco, & McWayne, 2005). The EDI is used regularly across Canada and has been used in many countries including the United States of America, Australia, Chile, Holland, Jamaica, Kosovo, and New Zealand.

Teachers and caregivers in all CPSE waves completed a short form version of the full EDI (S-EDI; Janus, Duku, & Stat, 2005). The OCCS developed the S-EDI by conducting a factor analysis of the 104 items on the long version of the EDI and retaining the three highest loading items for each of the school readiness subdomains. The S-EDI is composed of 48 core items and provides scores in five domains and 15 subdomains of school readiness. The *physical health and well-being* domain is composed of three subdomains including physical readiness for the school day, physical independence, and gross and fine motor skills. The *social competence* domain comprises four subdomains including overall social competence with peers, responsibility and respect, approaches to learning, and readiness to explore new things. The *emotional maturity* domain consists of four subdomains including prosocial and helping behaviour, aggressive behaviour, anxious and fearful behaviour, and hyperactive and inattentive behaviour. The *language and cognitive development* domain contains four subdomains related to basic literacy skills, interest in literacy, numeracy, and memory, advanced literacy skills, and basic numeracy skills. The final construct, *communication and general knowledge* comprises three items assessing the child's ability to tell a story, to use language effectively, and to communicate in an understandable way. For each domain of the S-EDI, ratings are converted to a scaled score

ranging from zero to ten. Higher scores indicate higher levels of behaviours associated with that specific domain. Sample items from this measure are reported in Table 2 of Appendix A.

In addition, one question assessing subjective teacher and caregiver ratings of school readiness was included in Wave 2 - 5 of CPSE data collection. Teachers and caregivers were asked '*In terms of school readiness, how would you have rated this/your child when he/she started school in September, [relevant academic year]?*' Teachers and caregivers were asked to indicate whether the child was *definitely ready*, *somewhat ready*, or *definitely not ready* for school. Including this question allowed for comparisons with the school readiness survey of children living in the PFL catchment area conducted by the Children's Research Centre in Trinity College Dublin in 2004 (Kiernan et al., 2008).

### ***6. Importance of School Readiness Domains***

Another addition to Wave 3, Wave 4 and Wave 5 was teacher and caregiver perceptions of the most and least important aspects of development for a child's school readiness. Specifically, teachers and caregivers were asked '*Which of the areas [below] do you think is the most important and least important for a child's school readiness?*' Respondents were presented with the options of *physical health and well-being*, *social competence*, *emotional maturity*, *language and cognitive development*, and *communication skills and general knowledge*. This question was included as previous research has found that teachers and caregivers often emphasise different areas of school readiness in rating importance. In addition, the results from Waves 1 and 2 of the CPSE indicated divergences in teacher and caregiver reports of school readiness, indicating the relevance of this question for the present cohort.

## **H. Internal Consistency of Psychometric Measures, Data Imputation, and Testing Procedures**

### ***1. Internal Consistency***

Combined cohort specific standardised coefficient reliability estimates (Cronbach, 1951) and intercorrelations for the standardised measures used in the CPSE survey are reported in Table 1. Cronbach alpha coefficients represent the internal consistency or reliability of psychometric

assessments, or the degree to which all items that comprise a domain or subdomain are measuring the same latent construct. Higher Cronbach alpha coefficients represent greater reliability or internal consistency of items that compose a domain or subdomain.

A Cronbach alpha coefficient of .70 or higher is often used as evidence that the items measure a latent construct (Nunnally, 1978). Overall, the majority of standardised scales reached an acceptable reliability, with many falling above .80. Both caregiver rated measures of well-being (WHO-5 and CES-D) evidenced high reliabilities in this cohort ( $\alpha > .90$ ) as did the PSDQ parenting domains ( $\alpha > .70$ ) and, therefore, these parent rated measures were retained in further analyses. As illustrated in Table 1, teacher ratings on the S-EDI demonstrated higher internal consistency, on average, than did parent reports. As the analyses of this report focus on the use of teacher reported child school readiness, teacher rated S-EDI domains and subdomains that did not reach a reliability of .65 or higher were excluded from further analyses. This resulted in the exclusion of three teacher rated school readiness subdomains: physical readiness for the school day ( $\alpha_{\text{Teacher}} = .56$ ), physical independence ( $\alpha_{\text{Teacher}} = .51$ ), and advanced literacy skills ( $\alpha_{\text{Teacher}} = .55$ ).

## ***2. Data Imputation***

Although the amount of missing data in both the teacher and caregiver CPSE surveys was low (less than 5%), interpolation methods were used to account for missing data in the caregiver reported psychometric scales to maximise the sample size retained for analyses. For the PSDQ, WHO-5, and CES-D, missing data were imputed using responses that caregivers provided on other items within that specific standardised scale. The method involved replacing missing items with the group mean for that item and then adjusting for random noise. As responses on the standardised measures were treated as continuous, it was possible to calculate means. Specifically, the average response to a given item was calculated for each of the four waves of data collection. Missing items were then replaced with the corresponding group mean for that wave of data collection. As replacement using only the group mean may lead to under-estimation of the variance, the missing data for standardised scales were imputed using the mean plus a random residual value. No more than 4% of data were imputed for any psychometric scale.

In cases where data were missing on single item measures, observations with missing data were excluded from that analysis. Missing data on the S-EDI measure were handled in line with recommendations by the OCCS. Specifically, 75% of all items for the *social competence*, *emotional maturity*, and *language and cognitive development* domains must be answered to derive a valid score for that domain. Similarly, 66.7% of items on the *physical health and well-being* and *communication and general knowledge* domains must be valid to derive a score for these areas of school readiness. On average, less than 2% of data were missing at the domain level of the teacher rated S-EDI.

### **3. Testing Procedures**

Data analysis proceeded in three steps. First, an analysis of the level of school readiness in the *PFL* catchment area was conducted, providing a description of the ratings of teacher and caregiver reported school readiness for each wave of data collection. This was followed by a statistical examination of differences in school readiness ratings based on reporter (teacher vs. caregiver) and wave of data collection. Specifically, changes in school readiness over the five year period were examined. Second, bivariate relationships examining observed differences in teacher ratings of school readiness were explored. As classical hypothesis tests such as the *t*-test, *F*-test, and chi-square test can be unreliable when the sample size is small, bivariate Monte Carlo permutation tests, based on 20,000 replications, were used to test whether the observed differences in S-EDI scores within the variables of interest (e.g., gender (male/female), education (high/low)) were statistically significant while controlling for wave of data collection. Cohen's *d* effect sizes (Cohen, 1988) were calculated to illustrate the size of the effect in terms of the pooled standard deviation adjusted for the sample sizes of groups (e.g., male/female) tested. Additionally, regression analyses examined relationships between continuous variables and teacher rated school readiness while controlling for wave of data collection. Third, in order to test which socio-demographic, health, and environmental factors were the most relevant in the context of school readiness, the factors that evidenced significant relationships in the bivariate Monte Carlo permutation analyses were included in a Seemingly Unrelated Regression (SUR) analysis. The SUR analysis estimated the unique contribution of each variable on all five S-EDI domains simultaneously. Estimating a set of seemingly unrelated regressions jointly as a system yields more efficient estimates than estimating them separately, especially as the correlation

among the errors rises and the correlation among the independent variables falls (Green, 2000). In order to test for the appropriateness of the SUR, the Breusch-Pagan test was performed. The use of SUR was motivated by the fact that it allows the residuals to be correlated across S-EDI domains. If the residuals were independent, then OLS would be a more appropriate technique. The Breusch-Pagan test of independence was performed for the SUR regression in order to test the null hypothesis of the independence of the residuals across equations. A rejection of the null hypothesis provides an indication that had OLS regressions been estimated, the estimates would be inconsistent, therefore justifying the choice of SUR modelling.

**Table 1** Standardised Cronbach Alpha Coefficients and Intercorrelations for Standardised Instruments used in the CPSE Survey

Domain/Subdomain	Teacher Ratings					Caregiver Ratings						
	N	1	2	3	4	5	N	1	2	3	4	5

<b>1. WHO-5</b> (high scores = greater well-being)							424	(0.90)	.56***			
<b>2. CES-D</b> (high scores = greater symptomology)							275	(0.91)				
<b>Parenting Styles and Dimensions</b>												
<b>1. Authoritative Parenting</b>							450	(0.81)				
<b>2. Authoritarian Parenting</b>							467	-.16**	(0.75)			
<b>3. Permissive Parenting</b>							502	-.15***	.36***	(0.71)		

Note. Cronbach standardised reliability coefficients appear in parentheses. N represents the number of observations used to calculate reliabilities for each domain or subdomain and it differs from the number of observations used in later analyses as the standardised reliability coefficients were calculated using listwise deletion at the item level. This resulted in excluding any observations with missing data in any of the items that comprise each domain or subdomain. This technique provided the most appropriate test of internal consistency as only observations in which every item was answered were retained to assess the internal reliability of that domain or subdomain.

<sup>†</sup>These subscales were reverse coded to derive the Emotional Maturity domain.

## Results

### I. CPSE Cohort Descriptive Statistics<sup>1</sup>

#### 1. Teacher Characteristics

In general, primary schools teachers in the *PFL* catchment area do not teach the Junior Infant class consecutively, thus none of the teachers completing the survey in Waves 1 and 2 were the same. However, seven of the nine Junior Infant teachers who participated in Wave 3 also participated in Wave 1 of the CPSE survey and six of the teachers who participated in Wave 4 also participated in previous waves (one in Wave 3, three in Wave 2 and two in Wave 1). In Wave 5 one of the teachers had participated in Wave 2 and three of the teachers had also participated in Wave 3.

**Wave 1:** In total, 12 teachers from five different schools completed the online questionnaire for students in their class who had parental consent. On average, the teachers were 37 ( $SD^2=10.92$ ) years old and had been teaching for approximately 11 years. On average, teachers had just over four years of experience teaching Junior Infants. The amount of time spent teaching in the current schools ranged from one year to 31 years, with an average of approximately nine years. In terms of education, just over 58% of the teachers had a postgraduate qualification, one-third had a primary degree and 8% had a non-degree qualification. All participating teachers were female. Class size information was obtained for 58% ( $n^3=7$ ) of the teachers and ranged from 13 to 16 students, with an average of approximately 15 ( $SD=1.30$ ) students per class.

**Wave 2:** In the second wave, nine teachers from three schools participated. The average age of these teachers was 34 ( $SD=11.79$ ) years. On average, teachers had been in their profession for 12 years, they had spent 11 years teaching at their current school, and three years teaching Junior Infants. With respect to education, one-third of teachers had a postgraduate qualification, while

---

<sup>1</sup> Tables reporting the full descriptive statistics (mean, standard deviation, minimum and maximum values, and frequencies of categorical variables) for the variables reported in this section can be found in Tables 1 and 2 of Appendix B.

<sup>2</sup> *SD* signifies standard deviation and represents the typical distance of scores from the mean.

<sup>3</sup> *n* represents the number of observations/respondents who endorsed the response indicated.

56% had a primary degree, and 11% had a non-degree qualification. Class size ranged from 16 to 21, with an average of 18 ( $SD=1.73$ ) students per class.

**Wave 3:** In the third wave, nine teachers from three schools participated, with seven of them having participated in Wave 1 of data collection. On average, they were 35 ( $SD=9.68$ ) years old, they had been teaching for eight years, they had spent seven years teaching at their current school, and four years teaching Junior Infants. Two-thirds of participating teachers in Wave 3 had a postgraduate qualification, while the remaining one-third had a primary degree. Class size ranged from 13 to 17, with an average of 15 ( $SD=1.33$ ) students per class.

**Wave 4:** In the fourth wave, nine teachers from three schools completed the online questionnaire for students in their class who had parental consent. On average, they were 38 ( $SD=11.74$ ) years old, they had spent twelve years teaching at their current school, and four years teaching Junior Infants. In Wave 4, one third of the teachers had a postgraduate qualification, 56% had a primary degree and 11% had a non-degree qualification. All participating teachers were female. Class size ranged from 13 to 17, with an average of 14 ( $SD=1.30$ ) students per class.

**Wave 5:** In the fifth wave, seven teachers from three schools completed the online questionnaire for students in their class who had parental consent. On average, they were 29 ( $SD=4.05$ ) years old, they had spent eight years teaching at their current school, and three years teaching Junior Infants. Thirty six percent of the teachers had a postgraduate qualification, 64% had a primary degree and none had a non-degree qualification. All participating teachers were female. Class size ranged from 15 to 25, with an average of 20 ( $SD=4.25$ ) students per class.

## ***2. Caregiver Characteristics***

**Wave 1:** In total, 94 caregivers completed the CPSE pen and paper questionnaire assessing family socio-demographics, work life and finances, parenting styles and behaviours, and the school readiness of the Junior Infant child. The majority (94%,  $n=87$ ) of caregivers were the child's biological mother. The average age of caregivers was approximately 30 ( $SD=5.53$ ) years old and the majority were Irish (88%,  $n=81$ ), with 9.78% ( $n=9$ ) being Irish Travellers. This

corresponds to the 2006 Census data for the *PFL* catchment area which report that approximately 10% of the population in this area are Travellers. The highest level of education attained by the majority (55%) of caregivers was a Junior Certificate or lower. In terms of employment, 35% of caregivers were looking after the home or family and 39% were in some type of paid employment or training scheme, while 18% indicated they were unemployed.

**Wave 2:** In the second wave of data collection, 129 caregiver surveys were completed. Again, the majority of respondents (91%,  $n=116$ ) were the biological mothers, their average age was 32 ( $SD=6.72$ ) years, and the majority of caregivers described their ethnicity as Irish (87%,  $n=110$ ), while 8% ( $n=10$ ) were Irish Travellers. The highest level of education achieved by just under half (43%) of caregivers in Wave 2 was a Junior Certificate or lower. Twenty-eight percent of caregivers indicated they were looking after the home or family, 41% were in paid work or a paid training scheme, and 19% of caregivers in Wave 2 indicated they were unemployed.

**Wave 3:** A total of 106 caregiver surveys were completed in Wave 3. The majority of respondents (96%,  $n=102$ ) were the biological mothers, their average age was 31 ( $SD=5.86$ ) years old, and the majority described their ethnicity as Irish (92%,  $n=98$ ), and 5% ( $n=5$ ) were Irish Travellers. The highest level of education achieved by over half of caregivers (58%) in Wave 3 was a Junior Certificate or lower. Thirty-five percent of caregivers indicated they were looking after the home or family, 32% were in paid work or a paid training scheme, and 26% of caregivers in Wave 3 indicated they were unemployed.

**Wave 4:** In the fourth wave of data collection, a total of 105 caregiver surveys were completed. Similar to previous waves, the majority of respondents (93%,  $n=95$ ) were the biological mothers, their average age was 31 ( $SD=6.64$ ) years old, and the majority described their ethnicity as Irish (86%,  $n=86$ ), and 10% ( $n=10$ ) were Irish Travellers. The majority (54%) of caregivers had left education before completing the Leaving Certificate. In terms of employment status, 25% of caregivers indicated they were looking after the home or family, 38% were in paid work or a paid training scheme, and a further 30% of caregivers in Wave 4 described themselves as unemployed.

**Wave 5:** A total of 111 caregiver surveys were completed in Wave 5. Similar to previous waves the majority of respondents (88%,  $n=97$ ) were the biological mothers, their average age was 32 ( $SD=8.6$ ) years old, and the majority described their ethnicity as Irish (87%,  $n=96$ ), while 10% ( $n=11$ ) were Irish Travellers. The highest level of education attained by half (50%) of caregivers was a Junior Certificate or lower. In terms of employment, 25% of caregivers were looking after the home or family and 28% were in paid work or a paid training scheme, and 31% of caregivers in Wave 5 indicated they were unemployed.

### 3. *Child Characteristics*

**Wave 1:** The average age of children in the Wave 1 cohort was 4.83 ( $SD=0.46$ ) years old and 57% ( $n=59$ ) were male. Children had been in informal childcare (i.e., being looked after by grandparents, other relatives, or a nanny) for an average of approximately 22 ( $SD=10.1$ ) months and centre-based care for an average of 19 ( $SD=10.3$ ) months. Eighty-seven percent ( $n=87$ ) of participating children in Wave 1 lived in the *PFL* catchment area.

**Wave 2:** The average age of children in Wave 2 was 4.71 ( $SD=0.43$ ) years and 56% ( $n=74$ ) were male. Children in Wave 2 had been in informal childcare for an average of 35 ( $SD=19.40$ ) months and centre-based care for an average of approximately 21 ( $SD=10.9$ ) months. Eighty percent ( $n=106$ ) of participating children in Wave 2 resided in the *PFL* catchment area.

**Wave 3:** On average, children in Wave 3 were 4.67 ( $SD=0.40$ ) years old and 57% ( $n=63$ ) were male. Children in Wave 3 had been in informal childcare for an average of approximately 37 ( $SD=32.38$ ) months and centre-based care for an average of 21 ( $SD=10.39$ ) months. Seventy-four percent ( $n=81$ ) of participating children in Wave 3 lived in the *PFL* catchment area.

**Wave 4:** The average age of children in Wave 4 were 4.70 ( $SD=0.44$ ) years old and 49% ( $n=52$ ) were male. Children in Wave 4 had been in informal childcare for an average of approximately 26 ( $SD=17.25$ ) months and centre-based care for an average of 20 ( $SD=9.74$ ) months. Seventy-seven percent ( $n=81$ ) of participating children in Wave 4 lived in the *PFL* catchment area.

**Wave 5:** The average age of children in Wave 5 were 4.67 ( $SD=0.36$ ) years old and 46% ( $n=52$ ) were male. Children in Wave 5 had been in informal childcare for an average of approximately 28 ( $SD=11.97$ ) months and centre-based care for an average of 20 ( $SD=12.6$ ) months. Seventy seven percent ( $n=81$ ) of participating children in Wave 5 lived in the PFL catchment area.

#### **4. Household Characteristics**

##### **a) Number of Children and People in Household**

**Wave 1:** On average, just fewer than 5 people were living in each household, respondents had just under three biological children, and the Junior Infant child had, on average, just under two siblings living in the household.

**Wave 2:** Similar to Wave 1, approximately 5 people were living in each household, the respondent had just under three biological children and the Junior Infant child had, on average, 1.61 siblings living in the household.

**Wave 3:** On average, 4.6 people were living in each household, the respondent had just under three biological children and the Junior Infant child had, on average, 1.61 siblings living in the household.

**Wave 4:** On average, 4.8 people were living in each household, the respondent had on average 2.6 children and the Junior Infant had, on average, 1.51 siblings living in the household.

**Wave 5:** On average, 5.5 people were living in each household, the respondent had 2.5 biological children and the Junior Infant child had, on average, 1.31 siblings living in the household.

##### **b) Total Household Weekly Income and Social Welfare Payments**

**Wave 1:** Sixty percent ( $n=56$ ) of respondents provided information on their household weekly income, which includes income from all sources, social benefits, wages, salaries, dividends and

interest, unemployment insurance, the dole, worker's compensation, government pension, child benefit, and child support for every member of the household. Fifty-five percent of the cohort earned between €200 and €500 per week, with the largest category being those that took home between €300 and €400 per week (20%,  $n=11$ ). The majority of households (69%) in Wave 1 were in receipt of social welfare payments.

**Wave 2:** Fifty-four percent ( $n=70$ ) of respondents provided income information in the second wave of data collection. Sixty-seven percent of these respondents reported earning between €200 and €500 per week; with 21% ( $n=15$ ) reporting income between €300 and €400, and another 21% ( $n=15$ ) in the €400 to €500 weekly income bracket. The majority of households (64%) in Wave 2 were in receipt of social welfare payments.

**Wave 3:** Sixty percent ( $n=64$ ) of respondents provided income information in the third wave of data collection. Sixty-three percent of these respondents reported earning between €200 and €500 per week; with 22% ( $n=14$ ) reporting income between €300 and €400, and another 19% ( $n=12$ ) in the €400 to €500 weekly income bracket. Similar to Waves 1 and 2, the majority of households (74%) in Wave 3 were in receipt of social welfare payments.

**Wave 4:** Seventy percent ( $n=72$ ) of respondents provided income information in the fourth wave of data collection. Sixty-seven percent of these respondents reported earning between €200 and €500 per week; with 25% ( $n=19$ ) reporting income between €300 and €400, and another 18% ( $n=13$ ) in the €400 to €500 weekly income bracket. The majority of households (81.7%) in Wave 4 were in receipt of social welfare payments.

**Wave 5:** Eighty-eight percent ( $n=98$ ) of respondents provided income information in the second wave of data collection. Forty percent ( $n=39$ ) of these respondents reported earnings between €200 and €500 per week; with 16% ( $n=16$ ) reporting income between €300 and €400, and another 10% ( $n=9$ ) in the €400 to €500 weekly income bracket. Similar to previous waves, the majority of households (69%) in Wave 5 were in receipt of social welfare payments.

### **c) Medical Card, GP Visit Card, & Health Insurance**

**Wave 1:** Three quarters (75%,  $n=66$ ) of caregivers were in possession of a medical card, 12% ( $n=9$ ) were in possession of a GP Visit Card, and 5% ( $n=4$ ) of respondents had private health insurance.

**Wave 2:** Seventy-three percent ( $n=87$ ) of caregivers reported having a medical card, 11% ( $n=12$ ) reported having a GP Visit Card, and 6% ( $n=7$ ) had private insurance.

**Wave 3:** Seventy-five percent ( $n=76$ ) of caregivers reported having a medical card, 10% ( $n=9$ ) reported having a GP Visit Card, and 4% ( $n=4$ ) had private insurance.

**Wave 4:** Eighty percent ( $n=79$ ) of caregivers reported having a medical card, 12% ( $n=9$ ) reported having a GP Visit Card, and 7% ( $n=6$ ) had private insurance.

**Wave 5:** Eighty percent ( $n=86$ ) of caregivers reported having a medical card, 18% ( $n=17$ ) reported having a GP Visit Card, and 5% ( $n=5$ ) had private health insurance.

### **J. Comparison of CPSE Cohort Descriptive Statistics in Waves 1 to 5**

Differences between the teacher characteristics across the five waves of data collection did not reach significance. Specifically, differences regarding teacher age, years teaching, years teaching Junior Infants and years teaching at the current school did not reach significance across all waves of data collection, suggesting that the demographic characteristics of teachers were similar throughout each wave. This may be due to the high proportion of the same teachers across waves.<sup>4</sup>

In terms of caregiver characteristics, fewer caregivers in Wave 3 and 4 were at risk of poor well-being ( $p<.05$ ) according to the WHO-5 than caregivers in Wave 2 and Wave 5 (note that the

---

<sup>4</sup> As there was overlap in participating teachers, differences in teacher characteristics were further examined controlling for unique teacher effects using clustering. These results did not differ from the analyses presented here and are available upon request.

WHO-5 was not asked of caregivers in Wave 1). Differences in household characteristics between each wave of data collection did not reach significance, suggesting that the socio-demographic characteristics of families participating in the CPSE surveys were relatively similar across all four years.

### K. School Readiness in the CPSE Cohorts

Figure 1 illustrates the average teacher and caregiver reported scores on each of the five S-EDI domains compared to a Canadian norm for Waves 1, 2, 3, 4 and 5 of the CPSE survey. Results displaying tests of significant differences among raters and across waves are presented in Table 2.

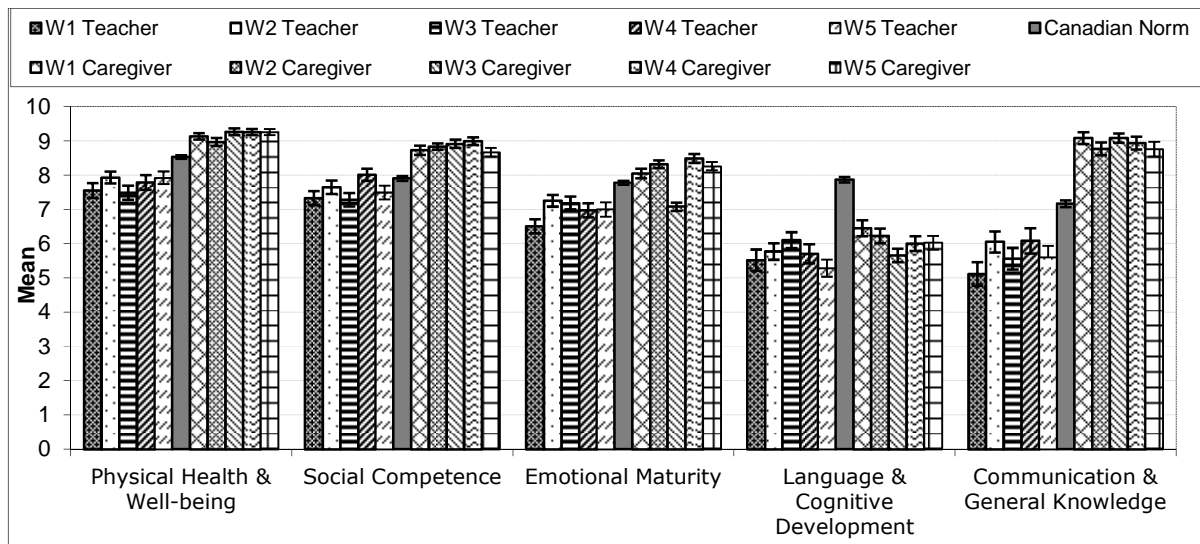

Figure 1. Average teacher and caregiver reported scores for all waves on each of the five S-EDI domains compared to a Canadian norm

#### 1. Comparisons of CPSE S-EDI and Canadian Norms

Teacher and caregiver ratings on each domain of the S-EDI also were compared to the ratings of the youngest subset of pupils from the teacher reported Canadian normative sample which includes 784 children ranging in age from four years and eleven months to five years and one month. The mean ratings and standard error of the mean for the Canadian norm are presented in the middle bar in Figures 2, 3, 4, 5 and 6.<sup>5</sup>

<sup>5</sup> Means represent the average response. Error bars represent standard error of the mean, or the amount of error in that measurement. Error bars can be used to visually evaluate differences between two means. Specifically, if the error bars for two means do not overlap, it is a good indication that these two means are statistically different from each other. For exact tests of differences, please refer to Table 2.

**Wave 1:** As illustrated in Figure 2 and Table 2, teacher rated school readiness of the Wave 1 CPSE cohort was consistently and significantly below the Canadian norm on all domains, while caregiver rated school readiness was significantly higher than the Canadian norms on the S-EDI domains of *physical health and well-being*, *social competence*, and *communication and general knowledge*. Conversely, caregivers rated *language and cognitive development* significantly lower than the Canadian norm. Differences between caregiver rated *emotional maturity* and the Canadian norms did not reach significance.

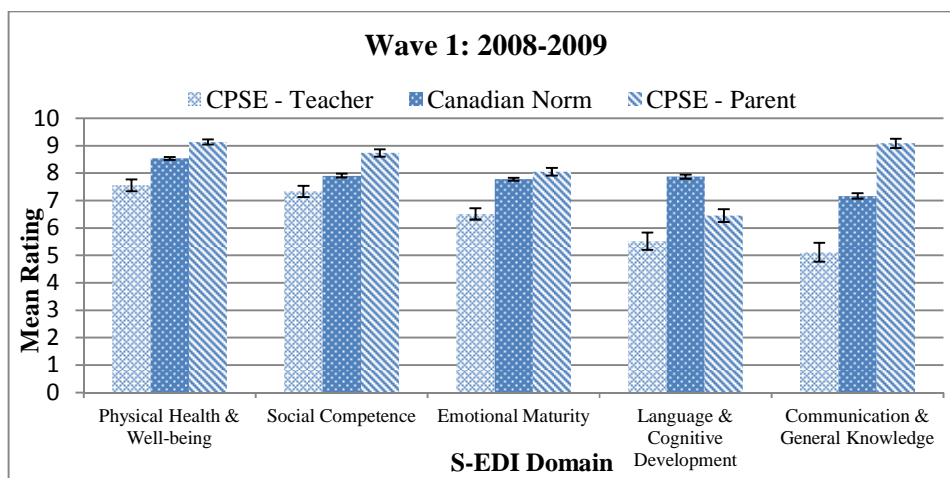

Figure 2. CPSE Wave 1 teacher, youngest subset of Canadian norm, and caregiver means and standard errors for each S-EDI domain.

**Wave 2:** Figure 3 and Table 2 show that, similar to Wave 1, teacher ratings were lower than the Canadian norm across all domains of school readiness. In terms of significant differences, teachers rated children in Wave 2 significantly below the Canadian norm on the *physical health and well-being*, *emotional maturity*, *language and cognitive development*, and *communication and general knowledge* domains, while caregiver ratings were significantly higher than the Canadian norm on the domains of *physical health and well-being*, *social competence*, *emotional maturity*, and *communication and general knowledge*. Additionally, and similar to Wave 1, caregivers rated children below the Canadian norm on the *language and cognitive development* domain. Differences between teacher ratings and the Canadian norm on the *social competence* domain did not reach significance.

Figure 3. CPSE Wave 2 teacher, youngest subset of Canadian norm, and caregiver means and standard errors for each S-EDI domain.

**Wave 3:** Figure 4 and Table 2 show that, similar to Waves 1 and 2, teacher ratings were significantly lower than the Canadian norm across all domains of school readiness. Differences between caregiver ratings and the Canadian norm, on the other hand, were mixed as caregivers rated children in Wave 3 significantly higher than the Canadian norm on the domains of *physical health and well-being*, *social competence*, and *communication and general knowledge*, while they rated children significantly lower than the Canadian norm on the domains of *emotional maturity* and *language and cognitive development*.

Figure 4. CPSE Wave 3 teacher, youngest subset of Canadian norm, and caregiver means and standard errors for each S-EDI domain.

**Wave 4:** Figure 5 and Table 2 show that, teacher ratings were significantly lower than the Canadian norm across the domains of *physical health and well-being*, *emotional maturity*,

*language and cognitive development* and *communication and general knowledge*. However, teacher ratings for the domain of *social competence* were not significantly different than the Canadian norm. Differences between caregiver ratings and the Canadian norm were mixed as caregivers rated children in Wave 4 significantly higher than the Canadian norm on the domains of *physical health and well-being*, *social competence*, *emotional maturity* and *communication and general knowledge*, while they rated children significantly lower than the Canadian norm on the domain of *language and cognitive development*.

Figure 5. CPSE Wave 4 teacher, youngest subset of Canadian norm, and caregiver means and standard errors for each S-EDI domain.

**Wave 5:** Figure 6 and Table 2 show that, teacher ratings were consistently and significantly below the Canadian norm on all domains of school readiness, while caregiver rated school readiness was significantly higher than the Canadian norms on the S-EDI domains of *physical health and well-being*, *social competence*, *emotional maturity* and *communication and general knowledge*. Conversely, caregivers rated *language and cognitive development* significantly lower than the Canadian norm.

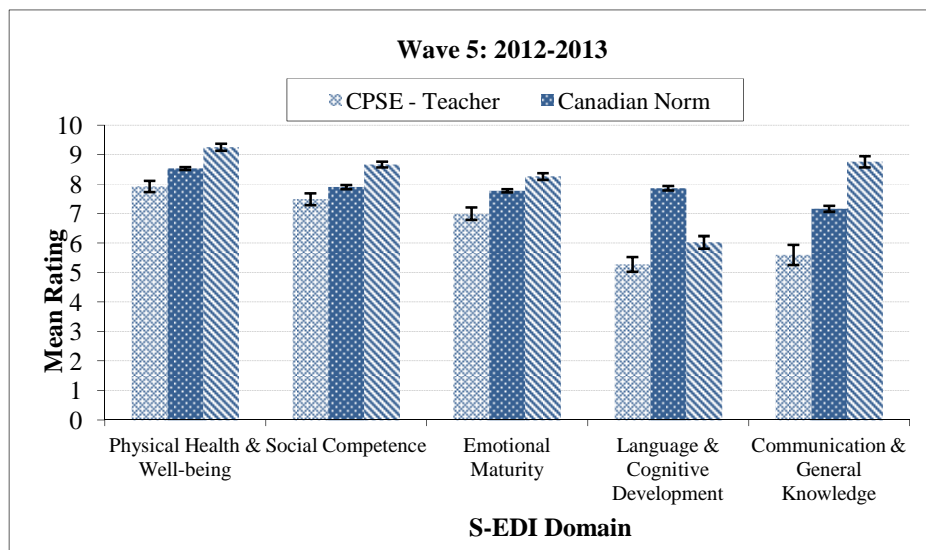

Figure 6. CPSE Wave 5 teacher, youngest subset of Canadian norm, and caregiver means and standard errors for each S-EDI domain.

## 2. Teacher Reported S-EDI

**Wave 1:** Teachers rated children in the 2008-2009 CPSE cohort highest on the *physical health and well-being* and *social competence* domains and lowest on the *language and cognitive development* and *communication and general knowledge* domains. Children's scores on each teacher reported S-EDI domain were generally all statistically significantly different from each other with two exceptions. First, differences between the teacher rated *physical health and well-being* domain and the teacher rated *social competence* domain did not reach significance and second, differences between the teacher rated *language and cognitive development* and *communication and general knowledge* domains did not reach significance.

**Wave 2:** Similar to the previous year, teachers in the 2009-2010 CPSE cohort rated children highest on the *physical health and well-being* and *social competence* domains and lowest on the *language and cognitive development* and *communication and general knowledge* domains. S-EDI domain scores were generally statistically different from each other. However, similar to Wave 1, no statistically significant differences were present between the *physical health and well-being* and *social competence* domains, or between the *language and cognitive development* and *communication and general knowledge* domains.

**Wave 3:** Teachers in the 2010-2011 CPSE cohort rated children highest on the *physical health and well-being* and *social competence* domains and lowest on the *language and cognitive development* and *communication and general knowledge* domains. S-EDI domain scores were generally statistically different from each other. However, similar to Waves 1 and 2, no statistically significant differences were identified between the *physical health and well-being* and *social competence* domains. In addition, differences in teacher ratings of *physical health and well-being* and *emotional maturity*, and between *social competence* and *emotional maturity* did not reach significance in Wave 3.

**Wave 4:** Teachers in the 2011-2012 CPSE cohort rated children highest on the *social competence* and *physical health and well-being* domains and lowest on the *language and cognitive development* and *communication and general knowledge* domains. S-EDI domain scores were generally statistically different from each other. However, similar to previous waves, no statistically significant differences were identified between the *physical health and well-being* and *social competence* domains. In addition, differences in teacher ratings of *language and cognitive development* and *communication and general knowledge* domains did not reach significance in Wave 4.

**Wave 5:** Teachers in the 2012-2013 CPSE cohort rated children highest on the *social competence* and *physical health and well-being* domains and lowest on the *language and cognitive development* and *communication and general knowledge* domains. S-EDI domain scores were generally statistically different from each other, including the *physical health and well-being* and *social competence* domains which were not observed in previous waves. However, similar to previous waves, no statistically significant differences were identified between the *language and cognitive development* and *communication and general knowledge* domains.

### **3. Caregiver Reported S-EDI**

**Wave 1:** Caregivers rated children highest in the domains of *physical health and well-being* and *communication and general knowledge* and lowest on the *language and cognitive development*

domain. Children's scores on each caregiver rated S-EDI domain were significantly different from each other, with the exception that the differences between caregiver rated *physical health and well-being* and *communication and general knowledge* domain did not reach significance.

**Wave 2:** Caregiver ratings were highest for the *physical health and well-being*, *social competence*, and *communication and general knowledge* domains. Like the previous wave, caregivers rated the children lowest on the *language and cognitive development* domain. In general, the scores for each domain were different from each other. However, differences between the following domains did not reach statistical significance: *physical health and well-being* and *social competence*; *physical health and well-being* and *communication and general knowledge*; *social competence* and *communication and general knowledge*.

**Wave 3:** Caregiver ratings were highest for the *physical health and well-being* and *communication and general knowledge* domains. Like the previous waves, caregivers rated the children lowest on the *language and cognitive development* domain. In general, the scores for each domain were different from each other. However, differences between the *physical health and well-being* and *communication and general knowledge* domains did not reach significance.

**Wave 4:** Caregiver ratings were highest for the *physical health and well-being*, *social competence* and *communication and general knowledge* domains. Similar to previous waves, caregivers rated the children lowest on the *language and cognitive development* domain. Not all the scores for each domain were different from each other. Differences between the *physical health and well-being*, *social competence* and *communication and general knowledge* domains did not reach significance.

**Wave 5:** Caregiver ratings were highest for the *physical health and well-being*, *social competence* and *communication and general knowledge* domains. Similar to previous waves, caregivers rated the children lowest on the *language and cognitive development* domain. Not all the scores for each domain were different from each other. Differences between the *social competence* and *communication and general knowledge* domains did not reach significance.

#### 4. Comparisons of Teacher and Caregiver Reported S-EDI

**Wave 1:** Caregivers consistently rated children as displaying higher levels of school readiness compared to teachers. Specifically, caregiver ratings were significantly higher than teacher ratings on the S-EDI domains of *physical health and well-being*, *social competence*, *emotional maturity*, and *communication and general knowledge*. Additionally, trends in the data highlighted potential differences between teacher and caregiver reports of *language and cognitive development*. Note that the teacher and caregiver reports of several domains of school readiness follow similar patterns. For example, both teachers and caregivers rated children highest on the *physical health and well-being* domain. In contrast, caregivers rated children high on the *communication and general knowledge* domain, a domain that was rated low by teachers.

**Wave 2:** Similar to the first wave, caregiver ratings of children's school readiness were significantly higher than teacher ratings on the *physical health and well-being*, *social competence*, *emotional maturity*, and *communication and general knowledge* domains. Differences between teacher and caregiver ratings of the *language and cognitive development* domain did not reach significance.

**Wave 3:** Similar to the first two waves, caregiver ratings of children's school readiness were higher than teacher ratings on the *physical health and well-being*, *social competence*, and *communication and general knowledge* domains. Teacher ratings on *language and cognitive development*, however, were higher than parent ratings on this domain. Differences between teacher and caregiver ratings of the *emotional maturity* domain did not reach significance.

**Wave 4:** Similar to the other waves, caregiver ratings of children's school readiness were higher than teacher ratings on the *physical health and well-being*, *social competence*, *emotional maturity* and *communication and general knowledge* domains. Differences between teacher ratings and parent ratings on the *language and cognitive development*, domain did not reach significance.

**Wave 5:** Similar to the other waves, caregiver ratings of children’s school readiness were generally higher than teacher ratings. However, in wave 5 caregiver ratings of children’s school readiness were significantly higher on all domains of school readiness than teacher ratings.

### 5. Comparisons of CPSE Waves 1 to 5<sup>6</sup>

Figures 7 and 8 illustrate several similarities in the patterns of mean scores across the five waves of data collection.

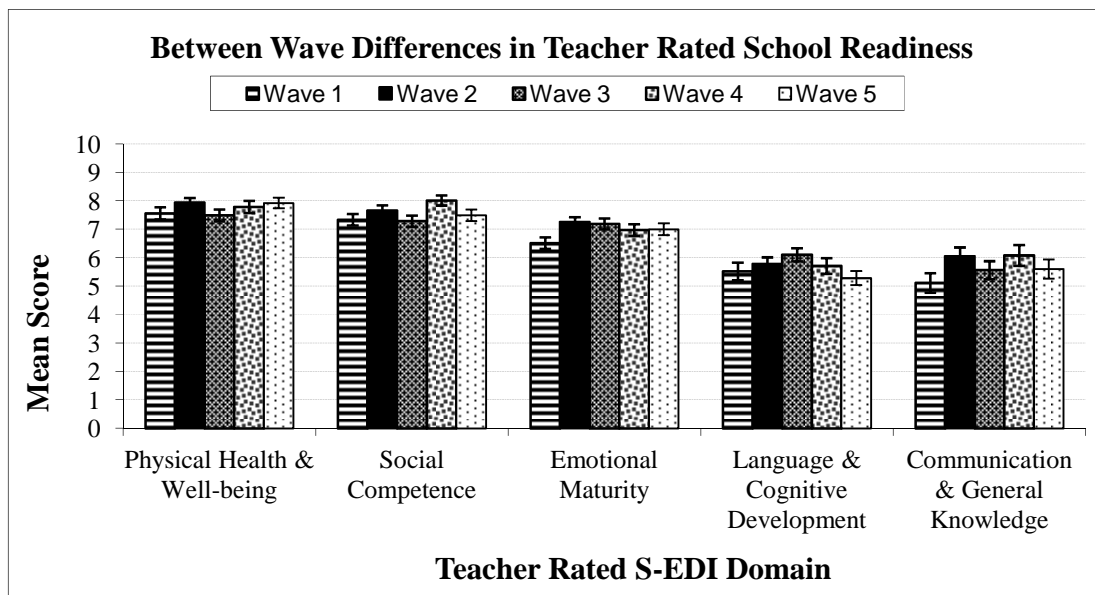

Figure 7. Between wave differences on teacher rated S-EDI school readiness domains.

<sup>6</sup> As the PFL catchment area expanded in 2009, one additional school, which is located in the expanded catchment area, was included beginning with Wave 2 data collection. Because of the different eligibility criteria across the first two waves of data collection, it was important to determine if the addition of this school influenced the comparison of Wave 1 and Wave 2 data. This was examined in detail in the CPSE 2008-2010 report and results of this analysis are available upon request and on the PFL Evaluation website. This analysis demonstrated that the results in the restricted sample which only included the schools in the original PFL catchment area were consistent with the results including data from all schools, suggesting that the children in the additional school did not differ from those in the original schools located in the original PFL catchment area. Therefore, as both groups were deemed comparable in Waves 1 and 2, the full sample was retained in the present report.

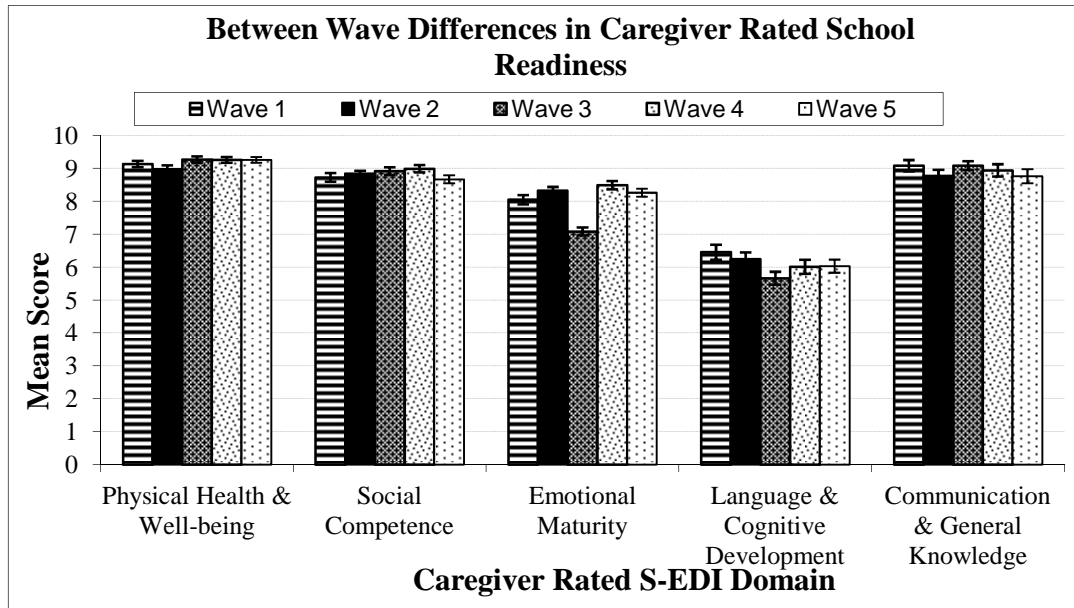

Figure 8. Between wave differences for caregiver rated S-EDI school readiness domains.

#### a) General Comparison of Mean Scores

Several similarities in the patterns of mean scores were present across all waves of data collection. Specifically, in all waves, teacher ratings were highest for the *physical health and well-being* and *social competence* domains and lowest for the *language and cognitive development* and *communication and general knowledge* domains. In addition, caregiver ratings were similar across waves with caregivers rating children highest in the *physical health and well-being* domains and lowest in the *language and cognitive development* domain. In addition to the *physical health and well-being* domain, caregivers in Wave 2 and Wave 4 rated children high in the *social competence* domain, while caregivers in Wave 1, 3 and 5 rated children high in the *communication and general knowledge* domain.

#### b) Statistical Comparisons of Wave Differences<sup>7</sup>

An Analysis of Variance (ANOVA) statistical procedure, using the Tukey correction for multiple group comparisons was used to test for statistical differences in levels of school readiness across

<sup>7</sup> In addition to the results presented here, a series of analyses controlling for unique teacher effects were conducted. The joint effects of wave and unique teacher were not significant for any of the school readiness domains.

the five waves of data collection.<sup>8</sup> As displayed in the bottom two rows of Table 2, there were some differences based on wave of data collection in both teacher and caregiver reports of children's school readiness. In terms of teacher ratings, teachers rated children in Wave 1 lower on the *emotional maturity* domain than children in Waves 2, 3, 4 or 5. In addition, teacher ratings on the *social competence* domain were higher for Wave 4 than Waves 1, 2, 3 and 5. In terms of caregivers, caregivers rated children's *emotional maturity* lower in Wave 3 compared to Waves 1, 2, 4 or 5. Caregivers also rated *language and cognitive development* lower in Wave 3 compared to Waves 1 and 2. As there were some differences between responses across waves, the year in which data were collected was controlled for in the statistical tests that follow by including a Wave dummy variable, which statistically separated the effect of a different sample group (i.e., Wave) from the effect of the variable being tested (e.g., gender).

---

<sup>8</sup> As all S-EDI domains were non-normally distributed, both ANOVA and Kruskal-Wallis non-parametric tests were used. Results did not differ between the two analyses. Therefore, results of the ANOVA are reported here.

Table 2

Note. *Z* represents a *Z*-score and is the test statistic associated with the Wilcoxon signed-rank statistical test. *t* and *F* represent the test statistics associated with a *t*-test and *F*-test, respectively. *df* illustrates the degrees of freedom, or the number of independent scores, associated with the statistical test and *p* represents the *p*-value, a measure of statistical significance. *ns* denotes that differences did not reach significance.

## **L. Most Important and Least Important School Readiness Domains**

A question regarding teacher and caregiver perceptions of the most and least important domains of a child's school readiness was added to the Wave 3 survey to gain insight into the aspects of school readiness that teachers and caregivers viewed as being important.

**Wave 3:** For Wave 3 the largest percentage of teachers (35%) indicated *social competence* to be the most important developmental domain for school readiness and *physical health and well-being* was perceived to be the least important domain of development for the largest percentage of teachers (41%). Caregiver ratings, on the other hand, showed a distinctly different pattern. The largest percentage of caregivers (39%) rated the *physical health and well-being* domain to be most important and 35% of caregivers rated the *language and cognitive development* domain to be the least important developmental area for a child's school readiness.

**Wave 4:** For Wave 4 the largest percentage of teachers (44%) indicated *emotional maturity* to be the most important developmental domain for school readiness and similar to Wave 3, *physical health and well-being* was perceived by teachers to be the least important domain (33%). Consistent with Wave 3 findings, the largest percentage of caregivers (40%) rated the *physical health and well-being* domain to be most important and 35% of caregivers rated the *language and cognitive development* domain to be the least important developmental area for a child's school readiness.

**Wave 5:** For Wave 5 the largest percentage of teachers (40%) indicated *emotional maturity* to be the most important developmental domain for school readiness and, *physical health and well-being* was perceived by teachers to be the least important domain (46%). The largest percentage of caregivers (48%) rated the *physical health and well-being* domain to be most important and 44% of caregivers rated the *language and cognitive development* domain to be the least important developmental area for a child's school readiness.

Although it is difficult to make a strong conclusion from these data given the relatively small sample sizes, an interesting pattern emerges. Specifically, for Wave 3, teachers highlighted the importance of *social competence* and for Waves 4 and 5 they cited *emotional maturity*. Both these domains are non-cognitive skills. In contrast, caregivers perceived *physical health and well-being*, a domain rated least important by the largest percentage of teachers, to be most important for a child's school readiness at both Wave 3, 4 and 5.

### **M. Vulnerability Indicators**

Table 3 reports the percentage of children in the CPSE Waves 1, 2, 3, 4 and 5 cohorts who were rated above the Canadian norm on each of the five S-EDI domains and Table 4 shows the percentage of children who were rated in the lowest 10% of the Irish sample on multiple domains of school readiness, according to teacher reports of school readiness.

#### ***1. Percentage Scoring Above and Below the Canadian Norm***

**Wave 1:** Although the average teacher reported level of school readiness in the CPSE cohort was significantly below the Canadian norm, a number of CPSE children were performing above this norm in some domains. Specifically, teachers rated just under half (49.5%) of the CPSE Wave 1 cohort above the Canadian norm on the *physical health and well-being* and *social competence* domains. However, only about 30% of children were rated above the Canadian norm on the *emotional maturity*, *language and cognitive development* and *communication and general knowledge* domains, demonstrating specific areas of weakness for a large portion of the CPSE Wave 1 cohort.

**Wave 2:** Similarly, Table 3 shows that a number of CPSE children in the Wave 2 cohort were performing above the Canadian norm in some domains. Specifically, teachers rated just under half (45.5%) of the children in Wave 2 above the Canadian norm on the *physical health and well-being* domain and more than half (58.5%) of children in Wave 2 above the Canadian norm on the *social competence* domain. Additionally, teachers rated greater than 40% of children above the Canadian norm on the domains of *emotional maturity* and *communication and general knowledge*, a marked improvement from Wave 1. However, only 26% of children were rated

above the Canadian norm on the *language and cognitive development* domain, demonstrating that this may be a continued area of weakness for children in the CPSE cohort.

**Wave 3:** In line with teacher rated reports of school readiness for Waves 1 and 2, Table 3 shows that a number of children in the Wave 3 cohort were performing above the Canadian norm in some domains. Specifically, teachers rated half of the children in Wave 3 above the Canadian norm on the *social competence* domain and over 40% of children above the Canadian norm on the *physical health and well-being* and *emotional maturity* domains of school readiness. Additionally, teacher ratings showed that approximately 31% of children were performing above the normative sample on the *language and cognitive development* domain. Although this does not represent a large percentage of the cohort, it is important to note that this figure demonstrates an improvement on Wave 2 performance and is in line with teacher reports on this domain in Wave 1. Finally, teacher ratings indicated that approximately 32% of children performed above the Canadian norm on the *communication and general knowledge* domain, illustrating that more children in Wave 3 of data collection were experiencing difficulties in this domain compared to Wave 2.

**Wave 4:**

Table 3 shows that a number of children in the Wave 4 cohort were performing above the Canadian norm in some domains. Specifically, teachers rated 60% of the children in Wave 4 above the Canadian norm on the *social competence* domain and over 46% of children above the Canadian norm on the *communication and general knowledge* domain. This figure demonstrates a significant improvement on Wave 3 performance. Approximately 44% of children in Wave 4 were rated by their teachers above the Canadian norm on the *physical health & well-being* domain. Consistent with previous waves, teachers rated 43% of children above the Canadian norm on the *emotional maturity* domain in Wave 4. Finally, teacher ratings showed that approximately 28% of children were performing above the normative sample on the *language and cognitive development* domain. Although this does not represent a large percentage of the cohort, it is important to note that this figure is consistent with teacher ratings for children in the previous three cohorts.

### **Wave 5:**

Similarly, Table 3 shows that a number of children in the Wave 5 cohort were performing above the Canadian norm in some domains. Specifically, teachers rated 55% of the children in Wave 5 above the Canadian norm on the *social competence* domain and over 47% above the Canadian norm on the *physical health & well-being* domain. Approximately 39% of children in Wave 5 were rated by their teachers above the Canadian norm on the *emotional maturity* domain, which is lower than the previous three waves. 35% of children in Wave 5 were rated by their teachers above the Canadian norm on the *communication and general knowledge* domain. Finally, teacher ratings showed that approximately 19% of children were performing above the normative sample on the *language and cognitive development* domain, this illustrates that significantly more children in Wave 5 were experiencing difficulties in this domain compared to any other wave of data collection.

Table 3  
*Percentage of Teacher Rated CPSE Cohort above Canadian Norm on S-EDI Domains*

<b>S-EDI Domain</b>	<b>Wave 1</b>	<b>Wave 2</b>	<b>Wave 3</b>	<b>Wave 4</b>	<b>Wave 5</b>
	<b>% Above Canadian Norm</b>	<b>% Above Canadian Norm</b>	<b>% Above Canadian Norm</b>	<b>% Above Canadian Norm</b>	<b>% Above Canadian Norm</b>
Physical Health & Well-being	49.50	45.53	41.28	44.34	47.75
Social Competence	49.50	58.54	50.00	60.38	55.45
Emotional Maturity	30.30	43.90	42.59	42.86	39.45
Language & Cognitive Development	30.43	25.64	31.37	28.43	19.09
Communication & General Knowledge	28.71	40.65	32.11	46.23	35.45

## ***2. Index of Vulnerability***

A child is considered vulnerable in a particular domain of school readiness if he/she is rated within the lowest 10% of all children in the CPSE cohort (i.e., Waves 1, 2, 3, 4 and 5 combined) for that domain.

**Wave 1:** As demonstrated in Table 4, approximately 62% ( $n=63$ ) of children did not score in the lowest 10% of the combined CPSE cohort on any of the five S-EDI domains, according to teacher ratings. However, close to one-fifth (19%,  $n=19$ ) of the children scored low on one of the

five domains, with a further 9% ( $n=9$ ) scoring low on two domains. Seven percent ( $n=7$ ) of the cohort scored low on three out of five domains, while 1% ( $n=1$ ) scored low on four of the five S-EDI domains, and 2% ( $n=2$ ) were vulnerable on all five domains of school readiness.

**Wave 2:** Table 4 also shows that 77% ( $n=95$ ) of children in Wave 2 were not vulnerable on any domain of school readiness, while 11% ( $n=14$ ) scored low on one domain, 5% ( $n=6$ ) on two domains, 4% ( $n=5$ ) on three domains, just under 1% ( $n=1$ ) on four domains, and almost 2% ( $n=2$ ) scored low on all five domains.

**Wave 3:** Table 4 illustrates that 76% ( $n=84$ ) of children in Wave 3 were not vulnerable on any domain of school readiness, while 15% ( $n=17$ ) scored low on one domain, 4% ( $n=4$ ) on two domains, 4% ( $n=4$ ) on three domains, and 1% ( $n=1$ ) scored low on all five domains.

**Wave 4:** Table 4 also shows that 71% ( $n=75$ ) of children in Wave 4 were not vulnerable on any domain of school readiness, while 12% ( $n=13$ ) scored low on one domain, 11% ( $n=12$ ) on two domains, 3% ( $n=3$ ) on three domains, and 3% ( $n=3$ ) on four domains. None of the children in Wave 4 were vulnerable on all five domains of school readiness.

**Wave 5:** Table 4 also shows that approximately 65% ( $n=72$ ) of children in Wave 5 were not vulnerable on any domain of school readiness, while 18% ( $n=20$ ) scored low on one domain, 4.5% ( $n=5$ ) on two domains, 7% ( $n=8$ ) on three domains, 2% ( $n=3$ ) on four domains, and 2% ( $n=3$ ) on all five domains of school readiness.

Table 4  
Number of S-EDI Scales on which CPSE Cohort are Vulnerable

# Domains Vulnerable	Wave 1		Wave 2		Wave 3		Wave 4		Wave 5	
	<i>n</i>	%	<i>n</i>	%	<i>n</i>	%	<i>n</i>	%	<i>n</i>	%
None	63	62.38	95	77.24	84	76.36	75	70.75	72	64.86
One	19	18.81	14	11.38	17	15.45	13	12.26	20	18.02
Two	9	8.91	6	4.88	4	3.64	12	11.32	5	4.50
Three	7	6.93	5	4.07	4	3.64	3	2.83	8	7.21
Four	1	0.99	1	0.81	0	0	3	2.83	3	2.70
Five	2	1.98	2	1.63	1	0.91	0	0	3	2.70

Note. *n* represents the number of observations.

### 3. Comparisons of Waves 1, 2, 3, 4 and 5

Overall, these results are consistent with findings from the overall test of differences in the levels of school readiness for Waves 1, 2, 3, 4 and 5. In terms of children scoring above and below the Canadian norm, the percentage of children who scored above the norm varies considerably between the five waves of the CPSE cohort. Both the *social competence* and *communication and general knowledge* domains show an upward trend, with ratings for each wave higher than those reported in Wave 1. Whereas the *language and cognitive development* domain ratings decrease over time, with ratings for Waves 3, 4, and 5 lower than those reported in Wave 1. It is difficult to establish what trend exists in the *physical health and well-being* and *emotional maturity* domains over the five waves of data collection. Ratings for *physical health and well-being* decreased over Waves 2 and 3 but then increased over Waves 4 and 5. Conversely, ratings for *emotional maturity* increased between Waves 1 and 2, remained relatively stable over Waves 2, 3, and 4 and subsequently decreased in Wave 5. Finally, fewer children in Waves 2, 3 and 4 were vulnerable in any of the domains of school readiness compared to Waves 1 and 5. However, there are considerably more children vulnerable on two domains in Waves 1 and 4 than Waves 2, 3 and 5. These figures show no discernible pattern over time.

#### *Subjective School Readiness*

To facilitate comparisons with a study conducted in the *PFL* catchment area in 2004 by Kiernan et al. (2008), teachers in Waves 2 - 5 were asked to indicate if they felt that the child was ready for school when he/she arrived in September of that academic year. Table 5 shows that the ratings for Waves 2, 3, 4 and 5 of the CPSE cohort were similar to the ratings of children surveyed in the 2004-2005 academic year, with about half of the children being rated as definitely ready for school and a further half of the cohort being rated as not ready, at least to some degree. The percentage of children deemed *definitely ready* by teachers has marginally increased over the three waves since 2009. This suggests that there have been few improvements in children's school readiness, as reported by teachers, in the *PFL* communities over an eight year period.

Table 5  
*Teacher Subjective Ratings of School Readiness*

Rating	2004 (Kiernan et al., 2008)		2009 (CPSE Wave 2)		2010 (CPSE Wave 3)		2011 (CPSE Wave 4)		2012 (CPSE Wave 5)	
	<i>n</i>	%	<i>n</i>	%	<i>n</i>	%	<i>n</i>	%	<i>n</i>	%
Definitely Ready	42	47.72	45	47.87	57	52.29	58	56.31	61	54.95
Somewhat Ready	35	39.77	37	39.36	36	33.03	32	31.07	35	31.53
Definitely Not Ready	11	12.5	12	12.77	16	14.68	13	12.62	15	13.51

*Note.* *n* represents the number of observations.

### N. Use of Teacher Reported School Readiness<sup>9</sup>

Although both teacher and caregiver reports of school readiness were obtained, the remaining results discussed in the report are based on teacher reported school readiness, unless otherwise noted. Teacher reports were used for four main reasons:

1. Teachers have long been thought to be accurate assessors of a child's abilities (Heaviside & Farris, 1993) and by focusing on teacher reported school readiness, the results of this study can be readily integrated into the current literature as the majority of studies use teacher reported levels of school readiness (Rimm-Kaufman, Pianta, & Cox, 2000).
2. Teacher reported school readiness scores are used to help overcome problems of shared method variance that arise when you have the same person rating both the independent and dependent variables in analyses.
3. Teacher and caregiver ratings significantly differ across the majority of S-EDI domains. In particular, the CPSE children are rated significantly higher than the Canadian norms based on caregiver report. As the normative data are based on a representative sample of Canadian children, which includes children from all social backgrounds, one would expect, on average, the Canadian norms to be higher than the CPSE scores (as demonstrated in the CPSE teachers ratings) which are based on children from a designated disadvantaged community.

<sup>9</sup> Analyses based on caregiver reported school readiness are available upon request.

4. As illustrated in Table 1, teacher rated school readiness demonstrated greater reliabilities in this cohort than caregiver rated school readiness. While three teacher rated subdomains (physical readiness for the school day, physical independence, and advanced literacy skills) were excluded from further analyses due to their low reliability, 11 caregiver-rated domains or subdomains (physical health and well-being, physical readiness for the school day, physical independence, gross and fine motor skills, overall social competence with peers, responsibility and respect, approaches to learning, anxious and fearful behaviour, basic literacy skills, interest in literacy, numeracy, and memory, and basic numeracy) did not meet our reliability criteria of .65 or above.

## O. Factors Associated with School Readiness<sup>10</sup>

For the remaining analyses, data from all five waves are combined, and the wave of data collection is controlled for in all analyses. Any significant or trend level (i.e.,  $p < .10$ )<sup>11</sup> findings for the main five S-EDI domains and subdomains are discussed below. Throughout this section, effect sizes<sup>12</sup> are reported in parentheses next to any significant results discussed.

### 1. Child Age

The average age of all children in the CPSE cohort was 4.71 ( $SD=0.43$ ) years. Table 6 reports the regression analysis modelling school readiness as a function of child age.

Table 6  
*Regression Analyses Representing the Relationship between Teacher Rated School Readiness and Child Age while Holding Wave of Data Collection Constant*

Domain	<i>df</i>	<i>F</i>	$\beta$	<i>SE</i>
<i>Physical Health &amp; Well-being</i>	(5, 498)	2.30	0.48*	0.21
Gross and Fine Motor Skills	(5, 480)	3.42	1.23**	0.32
<i>Social Competence</i>	(5, 499)	3.44	0.60**	0.21
Overall Social Competence with Peers	(5, 499)	2.79	0.71*	0.30
Responsibility and Respect	(5, 499)	2.21	0.41	0.26
Approaches to Learning	(5, 499)	2.75	0.77**	0.26
Readiness to Explore New Things	(5, 480)	7.12	0.56**	0.21
<i>Emotional Maturity</i>	(5, 493)	2.26	0.26	0.21
Prosocial and Helping Behaviour	(5, 438)	1.95	0.92*	0.37
Aggressive Behaviour	(5, 488)	1.76	- 0.12	0.26
Anxious and Fearful Behaviour	(5, 499)	3.23	- 0.21	0.37
Hyperactivity and Inattention	(5, 494)	2.39	- 0.02	0.27
<i>Language &amp; Cognitive Development</i>	(5, 474)	2.33	0.82**	0.28
Basic Literacy Skills	(5, 494)	2.81	1.21**	0.36
Interest in Literacy/Numeracy/Memory	(5, 488)	1.69	0.18	0.28
Basic Numeracy Skills	(5, 492)	4.76	0.47	0.29
<i>Communication &amp; General Knowledge</i>	(5, 497)	1.19	0.54	0.37

*Note.* *df* illustrates the degrees of freedom, or the number of independent scores, associated with the statistical test. *F* represents the test statistic associated with the *F*-test,  $\beta$  signifies the beta coefficient, and *SE* represents the standard error of the beta estimate which illustrates the distance between the regression line and the actual data points.

<sup>10</sup> Results of statistically significant relationships at the trend level ( $p < .10$ ) or higher are described in this section. All permutation test results are presented in Tables 1-11 of Appendix C.

<sup>11</sup> The *p*-values represent the probability that the result obtained is due to chance rather than a true relationship between variables. Consistent with the literature, *p*-values below 0.05 (5%) are considered to be statistically significant in the present report.

<sup>12</sup> The following rule can be applied to interpreting effect sizes (Gravetter & Wallnau, 2004). A Cohen's *d* ranging from 0.0 to 0.2 is deemed a small effect (mean difference is less than .2 standard deviation), values ranging from 0.2 to 0.8 are considered to represent a medium effect (mean difference around .5 standard deviation), and values greater than 0.8 illustrate a large effect (mean difference greater than .8 standard deviation).

---

†  $p < .10$ . \* $p < .05$ . \*\* $p < .01$  \*\*\* $p < .001$

Child age was positively associated with several domains and subdomains of school readiness, such that older children display greater school readiness skills. Specifically, positive relationships were found between child age and the *physical health and well-being* domain, with significant findings in the *gross and fine motor skills* subdomain. Child age was also associated with a positive trend in the *social competence* domain, with the *overall social competence with peers*, *approaches to learning* and *readiness to explore new things* subdomains showing significance. Furthermore, positive relationships were found between child age and the *language and cognitive development* domain, a finding driven by the significant relationships on the *basic literacy skills* subdomain. Finally, although the overall *emotional maturity* domain was not significant, the *prosocial and helping behaviour* subdomain showed a positive association with child age. Collectively, these results suggest that older children displayed higher levels of school readiness.

## 2. Child Gender

Fifty-three percent ( $n=299$ ) of all children in the CPSE cohort were male. Figure 9 represents the mean teacher ratings for each domain of school readiness for *males* and *females* in the CPSE cohort.

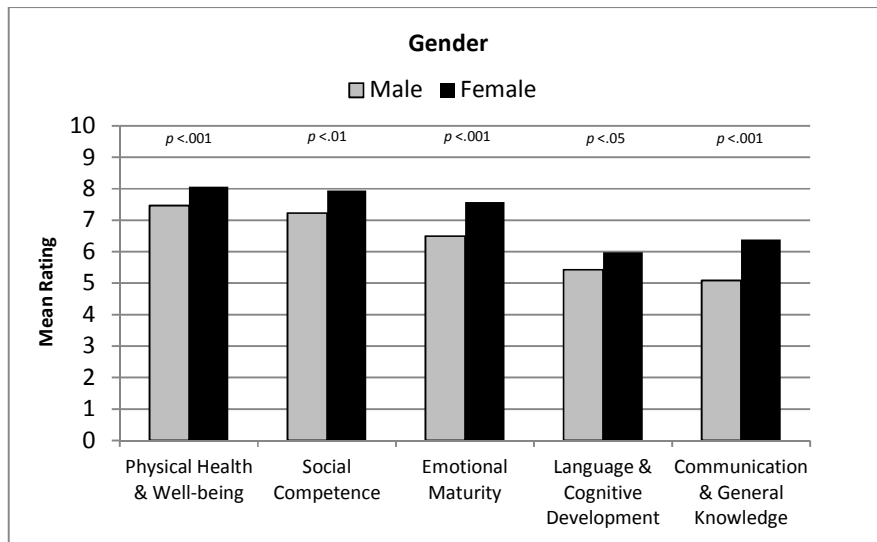

Figure 9. Differences in teacher reported S-EDI domains based on child gender.

Significant gender differences were present for the S-EDI domains of *physical health and well-being* ( $d=.30$ ), *social competence* ( $d=.36$ ), *emotional maturity* ( $d=.55$ ), *language and cognitive development* ( $d=.21$ ), and *communication and general knowledge* ( $d=.37$ ) such that girls were rated as displaying higher skills than boys. In terms of subdomains, gender differences in *gross and fine motor skills* ( $d=.40$ ), *overall social competence with peers* ( $d=.31$ ), *responsibility and respect* ( $d=.19$ ), *approaches to learning* ( $d=.41$ ), *readiness to explore new things* ( $d=.24$ ), *prosocial and helping behaviour* ( $d=.61$ ), *aggressive behaviour* ( $d=.30$ ), *anxious and fearful behaviour* ( $d=.38$ ), *hyperactivity and inattention* ( $d=.24$ ), *basic literacy skills* ( $d=.19$ ), *interest in literacy/numeracy/memory* ( $d=.28$ ) and *basic numeracy skills* ( $d=.20$ ) all reached significance, with girls displaying higher levels of school readiness than boys. Collectively, the results show moderate effect sizes with girls displaying higher levels of school readiness than boys.

## 3. Presence of Siblings

The number of siblings living in the same household as the Junior Infant child ranged from zero to seven, with an average of 1.56 ( $SD=1.36$ ) siblings. One hundred and twenty-three children

(23%) did not have any siblings living in the same household, while the majority of children (78%) had one or more siblings living in the same household. Figure 10 represents the mean teacher ratings for each domain of school readiness for children who *had siblings* living in the home and those who *did not have siblings*.

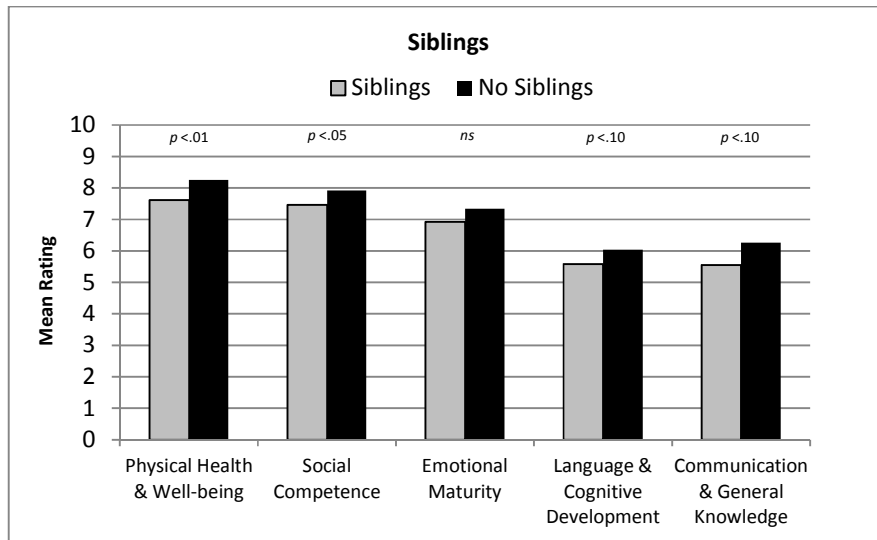

Figure 10. Differences in teacher reported S-EDI domains based on presence of siblings in household.

Children with no siblings in the household were rated as displaying significantly higher levels of *physical health and well-being* ( $d=.31$ ), and *social competence* ( $d=.23$ ) compared to children with at least one sibling living in the same household. Specifically, pupils without siblings displayed significantly more advanced *overall social competence with peers* ( $d=.26$ ), *responsibility and respect* ( $d=.24$ ), *basic literacy skills* ( $d=.14$ ). There were also findings which trended toward significance for the domains of *language & cognitive development* ( $d=.17$ ) and *communication and general knowledge* ( $d=.20$ ). Children with no siblings had somewhat better skills in the subdomains of *gross and fine motor skills* ( $d=.20$ ), *basic literacy skills* ( $d=.14$ ), and *basic numeracy skills* ( $d=.13$ ). Thus, children with no siblings living in the household demonstrated greater school readiness skills than those with siblings, with moderate effect sizes. In addition to examining the relationships between the binary variable representing if a child had siblings present in the household or not and school readiness, relationships between the total number of siblings living in the same household and school readiness were explored in a regression framework, while holding wave of data collection constant. Results demonstrated that,

not only does the presence of siblings matter, but so too does the number of siblings. Specifically, the number of siblings living in the household was negatively associated with all five domains and several subdomains of school readiness, such that children with more siblings living in the home display lower school readiness skills. Specifically, negative relationships were present between number of siblings living in the household and the *physical health and well-being* domain, with the *gross and fine motor skills* subdomain showing significance. Additionally, negative relationships were present for the *social competence* domain, with significant negative relationships existing between number of siblings and the *overall social competence with peers* and *readiness to explore new things* subdomains. Children with more siblings living in the household displayed lower levels of *emotional maturity*, especially in terms of *prosocial and helping behaviours*. In terms of *language and cognitive development*, negative relationships were present for the *basic literacy skills* and *basic numeracy skills* subdomains. Finally, there was a significant negative relationship demonstrating that children with more siblings were rated by teachers as displaying lower levels of *communication and general knowledge*. Collectively, these results echo the results presented in Figure 8 and suggest that having more siblings was associated with lower levels of school readiness in the CPSE cohort and demonstrate that not only does the presence of siblings in the household matter, but so too does the number of siblings.

Table 7  
*Regression Analyses Representing the Relationship between Teacher Rated School Readiness and Number of Siblings Living in the Household while Holding Wave of Data Collection Constant*

Domain	<i>df</i>	<i>F</i>	$\beta$	<i>SE</i>
<i>Physical Health &amp; Well-being</i>	(5, 521)	2.99	- 0.21**	0.07

Interest in Literacy/Numeracy/Memory	(5, 510)	2.21	- 0.15	0.09
Basic Numeracy Skills	(5, 514)	8.11	- 0.32**	0.09
<i>Communication &amp; General Knowledge</i>	(5, 520)	3.61	- 0.42***	0.11

*Note.* *df* illustrates the degrees of freedom, or the number of independent scores, associated with the statistical test. *F* represents the test statistic associated with the *F*-test,  $\beta$  signifies the beta coefficient, and *SE* represents the standard error of the beta estimate which illustrates the distance between the regression line and the actual data points.

†  $p < .10$ . \* $p < .05$ . \*\* $p < .01$  \*\*\* $p < .001$

#### 4. Caregiver Relationship Status

In regards to caregiver relationship status, 38% ( $n=202$ ) of caregivers reported they were single, 30% ( $n=158$ ) were married, and 21% ( $n=109$ ) were living with their partner. Thirty-two participants (6%) had a partner they were not living with and approximately 5% ( $n=27$ ) were separated, divorced, or widowed.

To determine whether child school readiness differed depending on caregiver relationship status two categories were derived. *Single* comprises respondents who indicated they were single, legally separated, divorced, or widowed and being *in a relationship* represents those who were married, cohabitating, or had a partner with whom they were not living at the time of the survey. In the cohort, 43% ( $n=229$ ) were classified as being single. Figure 11 represents the mean teacher ratings for each domain of school readiness for children of caregivers who were single and those who were in a relationship.

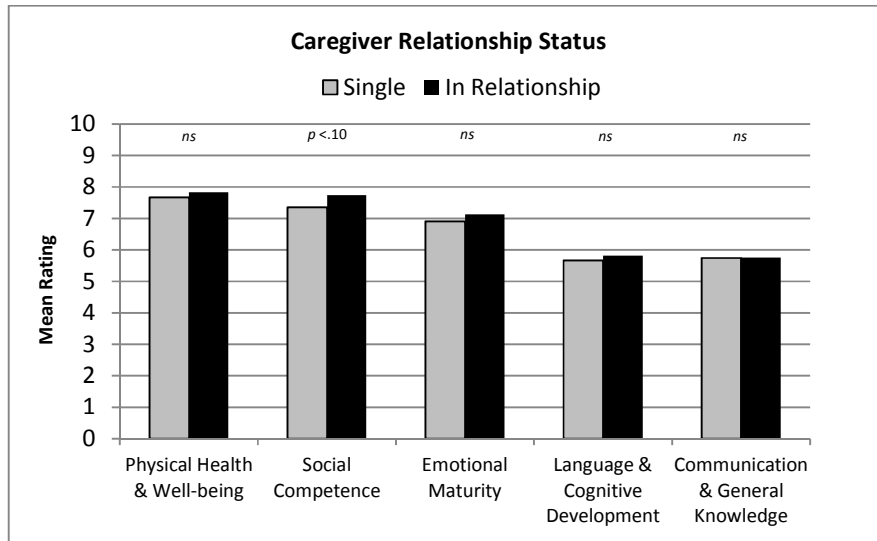

Figure 11. Differences in teacher reported S-EDI domains based on caregiver relationship status.

The associations between the S-EDI domains and relationship status of the caregiver did not reach statistical significance for any domain or subdomain. The domain of *social competence* ( $d=.19$ ) trended toward significance and the subdomain of *approaches to learning* ( $d=.23$ ) was significant. Therefore, relationship status of the caregiver was not highly associated with child school readiness.

### 5. Caregiver Age

The mean age of caregivers was approximately 31 years old ( $SD=6.81$ ), with ages ranging from 21 to 54 years.

Analyses were conducted to examine whether the school readiness skills of children of young caregivers differed compared to children of older caregivers. To achieve this, caregivers were divided into two groups based on their age when the Junior Infant child was born. The first group consisted of those who were *20 years old or younger* when the child was born and the second group consisted of those who were *older than 20 years* when the child was born. In the cohort, 18% ( $n=84$ ) were classified as being a young parent. Figure 12 represents the mean teacher ratings for each domain of school readiness for children of caregivers who were 20 years old or younger when the child was born and children of caregivers who were older than 20 years old when the child was born.

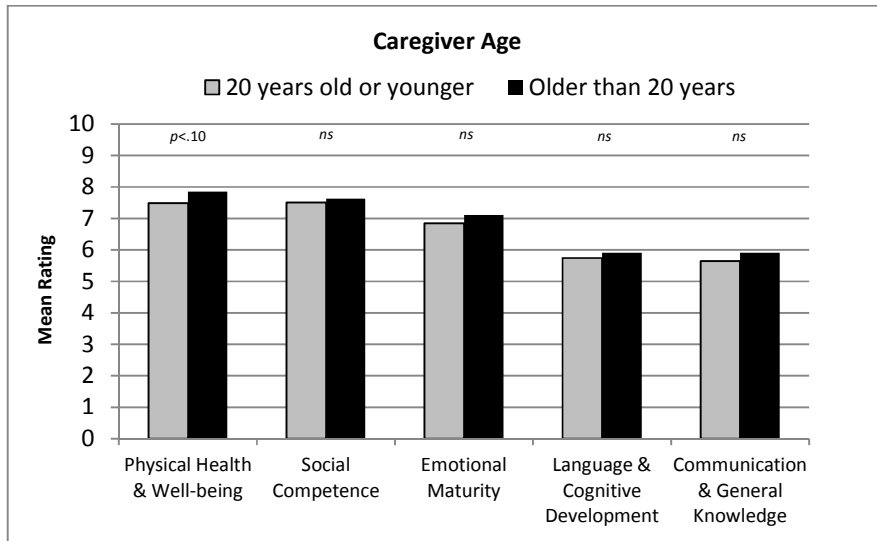

Figure 12. Differences in teacher reported S-EDI domains based on caregiver age at child's birth.

The associations between the S-EDI domains and caregiver age did not reach statistical significance for any domain or subdomain. A trend effect was shown in the *physical health and well-being* domain ( $d=.17$ ), illustrating that children of older caregivers displayed higher levels of physical health than children of younger caregivers. Overall, the age of the caregiver at the child's birth was not strongly associated with the child's school readiness.

In addition to examining the relationships between the young caregiver binary variable and school readiness, relationships between the continuous variable of caregiver age and school readiness were explored in a regression framework, while holding wave of data collection constant. As demonstrated in Table 8, no significant relationships emerged, further illustrating that caregiver age has little effect on a child's school readiness skills.

Table 8  
*Regression Analyses Representing the Relationship between Teacher Rated School Readiness and Caregiver Age while Holding Wave of Data Collection Constant*

Domain	<i>df</i>	<i>F</i>	$\beta$	<i>SE</i>

†  $p < .10$ . \* $p < .05$ . \*\* $p < .01$  \*\*\* $p < .001$

## 6. Caregiver Education

The highest level of education attained by 29% ( $n=152$ ) of the CPSE caregivers was the Junior/Group/Inter Certificate and the average school leaving age was 17 years old. Approximately 15% ( $n=79$ ) of caregivers completed upper secondary education, while 17% ( $n=90$ ) completed the Applied Leaving Certificate or Leaving Certificate. Twelve percent ( $n=60$ ) of caregivers had a non-degree qualification, 2% ( $n=12$ ) completed a primary degree and 5 respondents had completed a postgraduate qualification.

The educational categories were combined to enable a comparison between children of relatively low and high educated caregivers in this cohort. The low education group consisted of caregivers who did not attend school, had primary education, or lower secondary education. Note that the respondents in the low education group did not have a Junior Certificate. The *low education*

categorisation comprises approximately 21% ( $n=111$ ) of the sample. For purposes of these analyses, the *high education* categorisation included all caregivers who had reached their Junior Certificate or higher and represents approximately 79% ( $n=406$ ) of the total sample. Figure 13 represents the mean teacher ratings for each domain of school readiness for children of caregivers with low and high education.

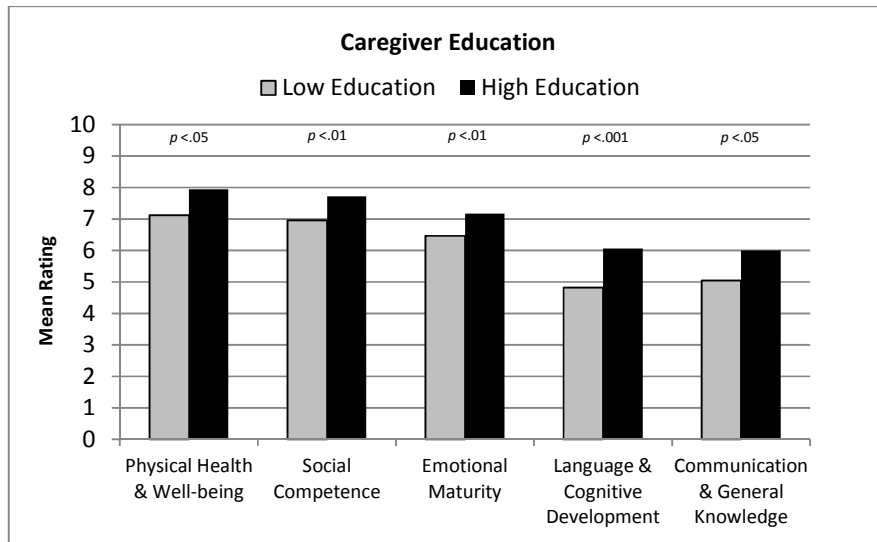

Figure 13. Differences in teacher reported S-EDI domains based on caregiver education.

Figure 9 demonstrates that children of caregivers with relatively higher levels of education were rated by teachers as displaying higher levels of school readiness in all domains. Specifically, children of relatively higher educated caregivers displayed higher levels of *physical health and well-being*, ( $d=.40$ ) *social competence* ( $d=.37$ ), *emotional maturity* ( $d=.35$ ), *language and cognitive development* ( $d=.47$ ) and *communication and general knowledge* ( $d=.27$ ).

Additionally, they had higher levels of *gross and fine motor skills* ( $d=.35$ ) and were significantly more socially competent in regards to *overall social competence with peers* ( $d=.29$ ), *responsibility and respect* ( $d=.30$ ), *approaches to learning* ( $d=.32$ ) and *readiness to explore new things* ( $d=.27$ ). Children of caregivers with relatively higher levels of education displayed significantly less *aggressive behaviour* ( $d=.30$ ) and less *anxious and fearful behaviour* ( $d=.38$ ). A trend was also found for the subdomain *prosocial and helping behaviours* ( $d=.24$ ). The data also suggested that children of caregivers with relatively higher education displayed higher levels of *basic literacy skills* ( $d=.42$ ), *interest in literacy, numeracy, and memory* ( $d=.23$ ) and *basic*

*numeracy skills* ( $d=.32$ ). Collectively, these results indicated that children of caregivers with relatively higher levels of education displayed higher levels of school readiness, with moderate effect sizes identified.

### **7. Caregiver Employment Status<sup>13</sup>**

The largest number of caregivers (30%,  $n=152$ ) in the cohort were looking after their home or family, 27% ( $n=137$ ) were in paid work, 3% ( $n=14$ ) were on leave from paid work, 26% ( $n=130$ ) were unemployed, 9% ( $n=45$ ) were in paid FAS training, less than 1% ( $n=3$ ) were in unpaid FAS training, 2% ( $n=8$ ) were not able to work due to permanent disability, and less than 1% ( $n=4$ ) indicated that they were a student. Of the caregivers who were currently in paid work, including those participating in a paid FAS training scheme, 93% ( $n=183$ ) provided information on the number of hours worked. The average number of hours worked per week was 25.75 ( $SD=10.14$ ).

Employment status was divided into two categories for further analyses based on those *not in paid work* and those *in paid work*, at least part time (including paid training courses). Approximately 41% ( $n=196$ ) of the cohort were in paid work. Figure 14 represents the mean teacher ratings for each domain of school readiness for children of caregivers not in paid work and children of caregivers in paid work.

---

<sup>13</sup> Note that the majority (93%) of respondents were biological mothers of the children, thus these figures largely represent the employment status of mothers.

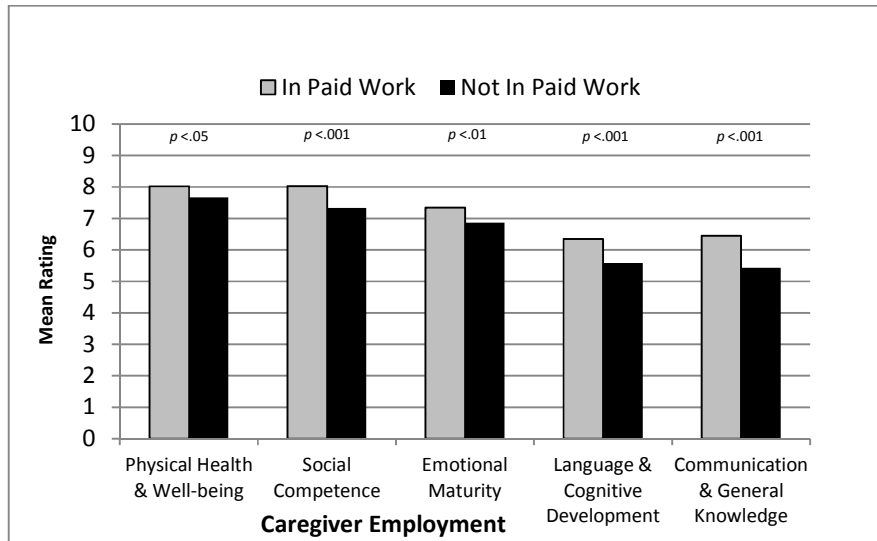

Figure 14. Differences in teacher reported S-EDI domains based on caregiver employment status.

Figure 10 shows that children of caregivers in paid work were rated as showing significantly higher levels of *physical health and well-being*, ( $d=.17$ ) *social competence* ( $d=.35$ ), *emotional maturity* ( $d=.24$ ), *language and cognitive development* ( $d=.29$ ) and *communication and general knowledge* ( $d=.29$ ) than children of caregivers not in paid work. Specifically, children of caregivers in paid work displayed higher *overall social competence with peers* ( $d=.32$ ), *responsibility and respect* ( $d=.20$ ), *approaches to learning* ( $d=.29$ ), *readiness to explore new things* ( $d=.32$ ), *prosocial and helping behaviour* ( $d=.21$ ), *basic literacy skills* ( $d=.20$ ), *interest in literacy, numeracy, and memory* ( $d=.30$ ), and *basic numeracy skills* ( $d=.24$ ). They also displayed less *anxious and fearful behaviour* ( $d=.24$ ). Additionally, trends in the data suggested that children of caregivers in paid work displayed higher levels of *gross and fine motor skills* ( $d=.14$ ) than children of caregivers not in paid work. Collectively, these results suggest that children of caregivers in paid employment appear better ready for school, with moderate effect sizes.

### 8. Caregiver Social Welfare Dependency

Almost three-quarters of the cohort (74%,  $n=344$ ) were receiving social welfare payments such as job seekers benefit, job seekers allowance, social welfare payments, rent allowance, or disability allowance. Social welfare is a good proxy for socio-economic status (SES) as there is often a high correlation between welfare dependency and SES indicators of low education,

income and social class. Figure 15 represents the mean teacher ratings for each domain of school readiness for children in families who were *in receipt of social welfare* payments and children of families who were *not in receipt of social welfare* payments.

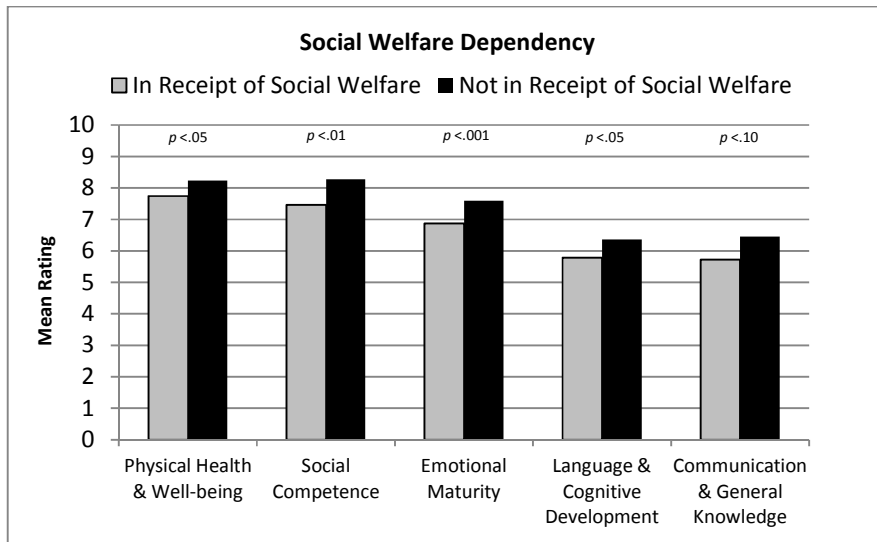

Figure 15. Differences in teacher reported S-EDI domains based on household social welfare dependency.

Children living in households not dependent on social welfare payments were rated by teachers as displaying higher levels of *physical health and well-being* ( $d=.25$ ), *social competence* ( $d=.41$ ), *emotional maturity* ( $d=.35$ ), *language and cognitive development* ( $d=.23$ ). Specifically children living in households not dependent on social welfare were rated higher by teachers in *overall social competence with peers* ( $d=.23$ ), *responsibility and respect* ( $d=.43$ ), *approaches to learning* ( $d=.37$ ) and *readiness to explore new things* ( $d=.26$ ), *prosocial and helping behaviour* ( $d=.21$ ), *basic literacy skills* ( $d=.23$ ), *interest in literacy numeracy and memory* ( $d=.21$ ) and *basic numeracy skills* ( $d=.24$ ) subdomains. Additionally they displayed significantly less *aggressive behaviour* ( $d=.42$ ) and less *anxious and fearful behaviour* ( $d=.32$ ). Differences in *communication and general knowledge* ( $d=.21$ ) trended toward significance. Therefore, social welfare status of the family appears to be associated with all domain but communication and general knowledge, with moderate effect sizes.

### 9. Caregiver Mental Well-being (WHO-5)

On average, caregivers rated their mental well-being as 15.74 ( $SD=6.07$ ) on a possible scale of zero to 25. This compares to a mean of 16.96 ( $SD=4.94$ ) in a representative cohort of Irish respondents (Delaney, Doyle, McKenzie, & Wall, 2009). Therefore, the CPSE cohort rated their mental well-being significantly below a representative Irish sample ( $t(2716) = 4.53, p < .001$ ), indicating the relatively poor mental health status of this cohort.

According to the developers of the WHO-5 scale, scores at or below 12 represent *low mental well-being* and scores of 13 or above represent *high mental well-being*. Twenty-nine percent ( $n=132$ ) of caregivers demonstrated low well-being and 71% ( $n=314$ ) were categorized as having high well-being according to this criterion. Figure 16 represents the mean teacher ratings for each domain of school readiness for children of caregivers with low and high mental well-being.

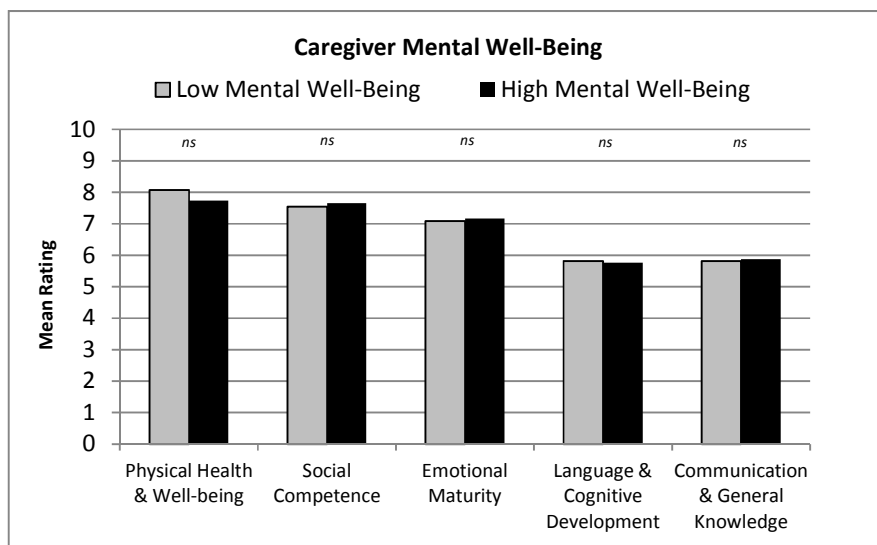

Figure 16. Differences in teacher reported S-EDI domains based on caregiver mental well-being.

There were no statistical differences on the main S-EDI domains or subdomains in regards to caregiver mental well-being. In sum, the mental well-being of the caregiver was not significantly associated with child school readiness.

In addition to examining the relationships between the binary well-being risk variable and school readiness, relationships between continuous caregiver well-being and school readiness were explored in a regression framework, while holding wave of data collection constant. In line with the finding reported using the binary well-being risk indicator, Table 9 finds no statistical relationship between mental well-being and school readiness.

Table 9

†  $p < .10$ . \* $p < .05$ . \*\* $p < .01$  \*\*\* $p < .001$

### **10. Caregiver Depressive Symptomology (CES-D)**

On average, caregivers reported a score of 9.16 ( $SD=9.40$ ) on a possible scale of zero to 60 in the CES-D measure of depressive symptomology. According to the developers of the CES-D scale, scores of 16 or higher represent high levels of depressive symptomology. Therefore, scores on the CES-D were dichotomised to represent *high symptomology* (total score  $\geq 16$ ) or *low*

*symptomology* (total score < 16). Eighty-one percent ( $n=255$ ) of caregivers demonstrated low depressive symptomology as measured by the CES-D and 19% ( $n=60$ ) reported high symptomology. Figure 17 represents the mean teacher ratings for each domain of school readiness for children of caregivers with high and low depressive symptomology.

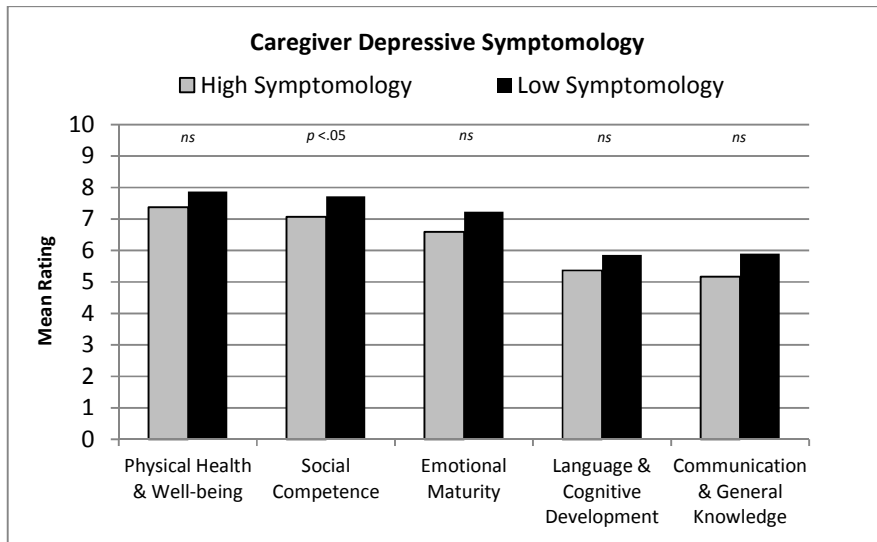

Figure 17. Differences in teacher reported S-EDI domains based on caregiver depressive symptomology.

Few differences in school readiness were present based on caregiver depressive symptomology. The only school readiness domain to reach statistical significance was *social competence* ( $d=.32$ ), with the *readiness to explore new things* ( $d=.42$ ), *hyperactivity and inattention* ( $d=.44$ ) subdomains reaching significance and the *approaches to learning* ( $d=.29$ ) subdomain showing a trend such that children of caregivers with lower depressive symptomology demonstrated lower levels of these behaviours, indicating they were more ready for school. Differences in all other domains and subdomains did not reach significance. In sum, depressive symptomology of the caregiver was not highly associated with child school readiness.

In addition to examining the relationships between the binary high depressive symptomology variable and school readiness, relationships between a continuous measure of depressive symptomology and school readiness were explored in a regression framework for children from Waves 3-5. As demonstrated in Table 10, significant relationships were present among caregiver

depressive symptomology and two of the domains of school readiness, *social competence* and *emotional maturity*. Specifically children of caregivers who report higher levels of depressive symptomology are rated lower by teachers in the *approaches to learning* and *readiness to explore new things* subdomains and are rated by teachers as displaying higher levels of *anxious and fearful behaviour*. A trend relationship was also identified, whereby children of caregivers who report higher levels of depressive symptomatology are rated as displaying higher levels of *hyperactivity and inattention*. Additionally, higher caregiver reported depressive symptoms showed trend level relationships with the *language and cognitive development* domain, a finding likely resulting from a trend relationship level relationship with the *basic literacy skills* subdomain.

†  $p < .10$ . \* $p < .05$ . \*\* $p < .01$  \*\*\* $p < .001$

## 11. Caregiver Self-Rated Health

Thirty-three percent ( $n=147$ ) of respondents indicated that their overall health was excellent, 39% ( $n=171$ ) stated that their health was very good, 24% ( $n=104$ ) indicated that it was good, 4% ( $n=18$ ) reported that their overall health was fair, and no caregiver reported being in poor health. For the purposes of this analysis, self-rated health was dichotomised to represent those who believed their health was *good* or *fair* and those who felt that their health was *excellent* or *very good*. Approximately 72% ( $n=318$ ) of the cohort indicated that they were in excellent or very good health. Figure 18 represents the mean teacher ratings for each domain of school readiness for children of caregivers who report good or fair health and children of caregivers who report excellent or very good health.

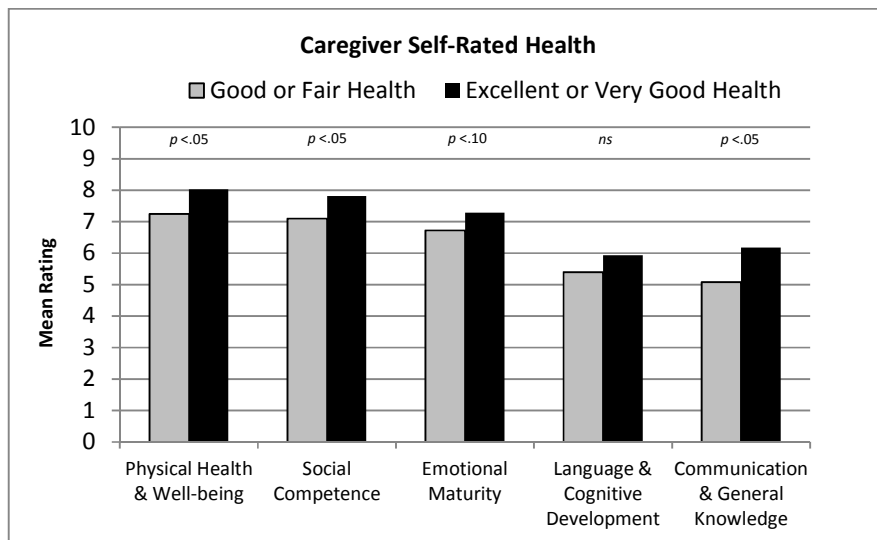

Figure 18. Differences in teacher reported S-EDI domains based on respondent self-reported health.

Three differences in school readiness were present based on self-rated health. Specifically, *physical health and well-being* ( $d=.39$ ), *social competence* ( $d=.35$ ) and *communication and general knowledge* ( $d=.32$ ) were all significantly higher for those children with parents who rated their health as excellent or very good. Additionally, children of caregivers who reported their health to be excellent were rated higher in terms of the *gross and fine motor skills* ( $d=.42$ ), *approaches to learning* ( $d=.43$ ) and *readiness to explore new things* ( $d=.29$ ) subdomains and lower on the *anxious and fearful behaviour* ( $d=.30$ ) subdomain. Finally, trend level effects were found for the *emotional maturity* ( $d=.28$ ) domain and *overall competence with peers* ( $d=.24$ ) and

basic numeracy skills ( $d=.25$ ) subdomains. Collectively, children of caregivers with higher self-reported health displayed higher levels of school readiness, with moderate effect sizes.

### 12. Participation in Centre-based Childcare

Caregivers provided information on whether their children had received any form of childcare prior to entering school, including being looked after by grandparents, relatives, other friends, a nanny, or attending crèche, nursery, preschool, or Montessori. The survey showed that 83% of children ( $n=463$ ) experienced some form of childcare prior to starting school, with 81% ( $n=449$ ) attending centre-based care. The children who received informal childcare in a home setting (either being looked after by grandparents, other relatives, or nannies) were in this type of care for, on average, 30.5 months ( $SD=20.7$ ). Children who received centre-based childcare either in a nursery or Montessori school spent 20.2 months ( $SD=10.3$ ), on average, in this type of childcare. Figure 19 represents the mean teacher ratings for each domain of school readiness for children in the CPSE cohort who *did not attend centre-based childcare* and those who *did attend centre-based childcare* at any period prior to school entry.

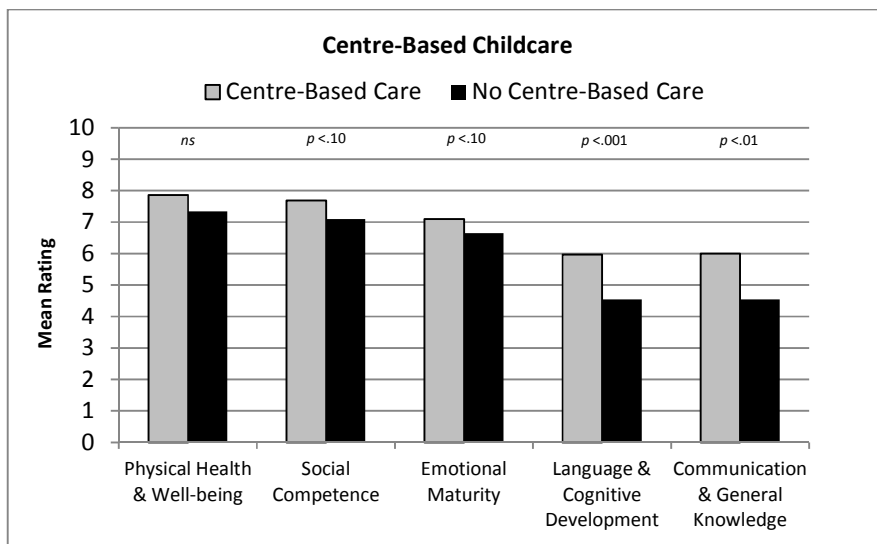

Figure 19. Differences in teacher reported S-EDI domains based on participation in centre-based childcare.

Differences on two of the five domains of school readiness, in addition to multiple subdomains, were present depending on whether a child participated in centre-based childcare prior to attending Junior Infants. Children who attended any form of centre-based care, for any period, prior to entering primary school, were rated as displaying significantly higher levels of *language and cognitive development* ( $d=.55$ ) and *communication and general knowledge* ( $d=.42$ ). The subdomains were significant for *gross and fine motor skills* ( $d=.34$ ), *readiness to explore new things* ( $d=.35$ ), *basic literacy* ( $d=.51$ ), *interest in literacy, numeracy, and memory* ( $d=.46$ ), *basic numeracy skills* ( $d=.31$ ), and *prosocial and helping behaviour* ( $d=.37$ ). Additionally trends were found in the *social competence* ( $d=.28$ ) and *emotional maturity* ( $d=.30$ ) domains and in the *approaches to learning* ( $d=.30$ ) subdomain. Therefore, children who participated in centre-based childcare prior to school entry displayed higher levels of school readiness, especially in terms of cognitive skills, with moderate effect sizes.

In addition to examining the relationships between participation in centre-based childcare and school readiness, the duration spent in centre-based child care and school readiness was explored in a regression framework, while holding wave of data collection constant. As demonstrated in Table 11, significant relationships were present between duration in centre-based childcare and several domains and subdomains of school readiness. Specifically, children who spent a longer time in centre-based childcare displayed higher levels of *language and cognitive development*, specifically *basic literacy skills* and *basic numeracy skills*. The *communication and general knowledge* domain also reached significance. The *social competence* domain demonstrated a trend, probably driven by the significant relationship in the *readiness to explore new things* subdomain in combination with a trend relationship in the *overall social competence with peers*. Additionally, trend relationships were identified with several subdomains, whereby longer duration in centre-based childcare was associated with higher levels of *gross and fine motor skills* and *prosocial and helping behaviour*. Collectively, these results highlight that longer duration in centre-based childcare is associated with greater school readiness.

Table 11

*Regression Analyses Representing the Relationship between Teacher-rated School Readiness and Duration in Centre-based Childcare while Holding Wave of Data Collection Constant*

*Note.* *df* illustrates the degrees of freedom, or the number of independent scores, associated with the statistical test. *F* represents the test statistic associated with the *F*-test,  $\beta$  signifies the beta coefficient, and *SE* represents the standard error of the beta estimate which illustrates the distance between the regression line and the actual data points.

†  $p < .10$ . \* $p < .05$ . \*\* $p < .01$  \*\*\* $p < .001$

### **13. Parenting Behaviours**

As demonstrated in Table 12, reports from the Parenting Styles and Dimensions Questionnaire showed that caregivers reported using a significantly higher level of authoritative parenting behaviours than authoritarian and permissive parenting behaviours, while they used a significantly higher level of permissive behaviours than authoritarian behaviours. The authoritative parenting style is characterised by warmth and support, while the authoritarian style is characterised by low responsiveness and high control. The permissive parenting style, although characterised by warmth, is one in which parents exert little control over children.

Table 12  
*Wilcoxon Signed-rank Results for Comparisons of Parenting Behaviours*

Comparison	Z	p
Authoritative vs. Authoritarian	20.15	<.001
Authoritative vs. Permissive	19.86	<.001
Permissive vs. Authoritarian	15.43	<.001

Note. Z represents the z-score or test statistic and p represents the p-value or significance level associated with the statistical test.

As displayed in Table 13, four discernible relationships emerged between parenting behaviours and teacher reports of school readiness. First, authoritarian parenting behaviours were negatively associated with teacher reports of *overall social competence with peers* and *responsibility and respect*. Second, permissive parenting behaviours were negatively associated with *basic literacy skills* and *social competence*, specifically, *responsibility and respect* and *approaches to learning*; while they were positively associated with *aggressive behaviour* and *anxious and fearful behaviour*. Finally, five trend level relationships were identified. Specifically, trends suggested a negative relationship between authoritarian parenting behaviours and *social competence* and *emotional maturity* and positive trends were present between authoritarian parenting behaviours and *aggressive behaviour*. Negative trends were also found between permissive parenting behaviours and *overall social competence with peers* and *emotional maturity*. No trends were identified between authoritative parenting behaviours and any of the domains of school readiness. Collectively, these results demonstrate that greater use of parenting behaviours characterised by low responsiveness and high control as well as those characterised by high warmth and low control were associated with lower levels of school readiness. These findings illustrate the impact that a parent’s controlling behaviours have on a child’s readiness for school.

Table 13

## **P. Multivariate Analysis of Factors Associated with School Readiness**

Based on the results reported in the previous section, factors that were significantly related to children's S-EDI scores in the bivariate analyses were included in a Seemingly Unrelated Regression (SUR) analysis.<sup>14</sup> SUR is particularly efficient when the independent variables differ from one equation to the next as is the case in the present report as only factors significantly associated with the individual S-EDI domains are included in each model.

An analysis was conducted examining the factors associated with school readiness across all waves, while controlling for wave of data collection. The results, reported in Table 14, show that while some factors were significantly related to school readiness in a bivariate analysis, they were no longer significant in a multivariate context. However, there were several significant relationships which were consistent across domains.

### ***1. Model 1: Factors Associated with School Readiness Across Waves***

The bivariate analyses identified several factors associated with the five school readiness domains. A Seemingly Unrelated Regression (SUR) was estimated to test whether any observed associations between the socio-demographic, health, and environmental factors and the school readiness domains remained when all relevant variables were controlled for. Only factors that were significantly associated, at the 5% level or below, with an individual school readiness domain in the bivariate analyses were included in the multivariate SUR analysis discussed here, while controlling for wave of data collection. Table 14 reports the estimates from the SUR model, with the  $F$  statistics and  $R^2$  for each individual equation and the overall Breusch-Pagan test reported at the end of the table. As the SUR model estimated the impact of the independent variables on five S-EDI domains jointly, the sample size reported was lower than the individual permutation tests.

The Breusch-Pagan test of independence rejected the null hypothesis of independence of the residuals across the equations ( $\chi^2(10) = 906.60; p < .001$ ). Therefore, OLS estimates would have been inconsistent and the choice of SUR was justified. All five of the school readiness domains

---

<sup>14</sup> SUR is a special case of generalized least squares, which estimates a set of equations with cross-equation constraints imposed (Zellner, 1962). Specifically, it allows for the possibility that the residuals are correlated across each S-EDI domain.

were significant at the 10% level or below. Specifically, the *physical health and well-being* model ( $F(6, 299) = 1.86; p < .10$ ), *social competence* ( $F(10, 295) = 2.92; p < .01$ ), *emotional maturity* ( $F(8, 297) = 3.21; p < .01$ ), *language and cognitive development* ( $F(8, 297) = 2.01; p < .05$ ), and *communication and general knowledge* ( $F(7, 298) = 3.17; p < .01$ ) models all reached significance accounting for 4%, 8%, 8%, 6% and 7% of the variance, respectively.

The only factors which maintained significant relationships with multiple domains of school readiness in the SUR analysis were child gender, and being in receipt of social welfare. Specifically, being a male child was significantly associated with a 1.24 point (on a zero to ten scale) decrease in *communication and general knowledge* ( $p < .01$ ), a 0.90 point decrease in *emotional maturity* ( $p < .001$ ), and a 0.49 point decrease in *social competence* ( $p < .05$ ). For two of the five school readiness domains, a caregiver being in receipt of social welfare was associated with a .50 decrease in a child's *social competence* ( $p < .05$ ) and a .45 decrease on the *emotional maturity* domain ( $p < .05$ ).

Four other factors demonstrated significant relationships with at least one domain of school readiness at the 5% significance level or below. Specifically, an increase in child age was associated with a .29 increase in a child's teacher rated *social competence* ( $p < .05$ ). With respect to caregiver education, children whose parents had obtained at least a Junior Certificate qualification were more ready for school. Specifically, low education was associated with a .72 decrease in teacher rated *language and cognitive development* ( $p < .05$ ). Finally, the child of a caregiver who is in paid work was associated with a .66 point increase in *communication and general knowledge* ( $p < .05$ ). Being in centre-based care was not associated with any of the five S-EDI domains.

## Summary & Conclusion

School readiness is a multifaceted concept, encompassing several domains of development. As different areas of school readiness may have different relationships with child and family characteristics, it is important to measure each domain of school readiness separately. By doing this, one can gain a more comprehensive reflection of school readiness and the factors that influence a child's abilities at school entry.

The 2008-2013 CPSE report examined this holistic view of school readiness among a cohort of children living in a disadvantaged urban community of Ireland. For the purpose of this study, assessments of school readiness were obtained via teacher and caregiver reports using the short form of the Early Development Instrument. The Short Early Development Instrument (S-EDI; Janus et al., 2005) enabled the teacher and caregiver ratings of school readiness to be compared to a normative sample of Canadian children. Although arguments regarding cultural, social and economic differences between Canada and Ireland can be made, there is no available representative or comprehensive data on the school readiness of Irish children. However, as this research will be conducted over multiple periods, it is feasible to generate a mean for Irish children living in designated disadvantaged areas.

Research has highlighted the stability of EDI ratings across different groups of children (Guhn, Gaderman, & Zumbo, 2007) and the S-EDI has been used in Canada, the United States of America, Australia and several other countries illustrating its cross cultural utility and validity (e.g., Brinkman et al., 2007). In addition, by using the same S-EDI measure in multiple data collection waves, changes in school readiness within the *PFL* communities over time can be assessed.

The results of this report support the concept that school readiness is multidimensional in nature, encompassing several domains of development. It is important to note that several differences emerged for multiple domains of school readiness, further providing evidence for parents, schools, practitioners, and researchers to take a more holistic approach to the definition of school readiness and interventions designed to improve it. Additionally, these findings demonstrate the importance of many domains of development in preparing a child for success in school.

Therefore, multiple domains of school readiness should be targeted when designing programmes to promote the school readiness of young children.

#### **Q. School Readiness in the 2008-2009 CPSE Cohort (Wave 1)**

Several statistical differences emerged between teacher and caregiver rated school readiness and the Canadian norms in the first wave of CPSE. The general pattern shows that teachers rated children in the CPSE cohort as displaying significantly lower levels of school readiness than the Canadian norm, while caregivers rated children as displaying significantly higher levels of school readiness than the Canadian norm. The results show that caregivers rated children as displaying higher levels of *physical health and well-being*, *social competence*, *emotional maturity*, and *communication and general knowledge* than teachers. Although the difference between teacher and caregiver rated *language and cognitive development* was not significant, there was a trend to suggest that caregivers also rated their children higher in this domain. While, on average, children in the CPSE cohort scored below the norms across all domains based on the teacher reports, approximately half the cohort were performing above the norm in regards to *physical health and well-being* and *social competence* and one-third of the cohort scored above the norm in the other three domains.

#### **R. School Readiness in the 2009-2010 CPSE Cohort (Wave 2)**

In the second round of data collection, many statistical differences were also recorded between teacher and caregiver rated school readiness and the Canadian norms. The overall pattern was very similar to Wave 1, with teachers in Wave 2 rating children as performing below the Canadian norm, and caregivers rating children above the Canadian norm. Regarding caregiver and teacher ratings, there were significant mean differences on *all school readiness domains* apart from language and cognitive development, with caregivers rating children higher on most S-EDI domains. Based on the teacher reports, almost 60% of children performed above the norm on the *social competence* domain and approximately 40% scored above the norm on *the physical health and well-being*, *emotional maturity*, and *communication and general knowledge* domains. Yet only 26% of children scored above the norm on the *language and cognitive development* domain.

### **S. School Readiness in the 2010-2011 CPSE Cohort (Wave 3)**

In Wave 3, many similar statistical differences were also recorded between teacher and caregiver rated school readiness and the Canadian norms. The overall pattern of teacher rated scores was very similar to previous waves, with teachers in Wave 3 rating children as performing below the Canadian norm across *all domains of school readiness*. Caregiver ratings, however, were mixed with caregivers rating children above the Canadian norm on the domains of *physical health and well-being*, *social competence*, and *communication and general knowledge* and below the Canadian norm on the domains of *emotional maturity* and *language and cognitive development*. Regarding teacher and caregiver rating comparisons, caregivers rated children significantly higher than did teachers on the domains of *physical health and well-being*, *social competence*, *language and cognitive development*, and *communication and general knowledge*. Based on the teacher reports, 50% of children performed above the norm on the *social competence* domain and approximately 40% scored above the norm on the *physical health and well-being* and *emotional maturity* domains. Finally, 30% of children in Wave 3 scored above the norm on the *language and cognitive development* and *communication and general knowledge* domains according to teacher ratings.

### **T. School Readiness in the 2011-2012 CPSE Cohort (Wave 4)**

In Wave 4, many similar statistical differences also were recorded between teacher and caregiver rated school readiness and the Canadian norms. The overall pattern of teacher rated scores was very similar to previous waves, with teachers in Wave 4 rating children as performing below the Canadian norm on the domains of *physical health and well-being*, *emotional maturity*, *language and cognitive development* and *communication and general knowledge* and statistically equal to the Canadian norm on the domains of *social competence*. Caregivers rated children above the Canadian norm on the domains of *physical health and well-being*, *social competence*, *emotional maturity*, and *communication and general knowledge* and below the Canadian norm on the domain *language and cognitive development*. Regarding teacher and caregiver rating comparisons, caregivers rated children significantly higher than did teachers on all five domains of school readiness. Based on the teacher reports, 60% of children performed above the norm on the *social competence* domain and more than 40% scored above the norm on the *physical health and well-being*, *emotional maturity* and *communication and general knowledge* domains.

Finally, 28% of children in Wave 4 scored above the norm on the *language and cognitive development* domain according to teacher ratings.

#### **U. School Readiness in the 2012-2013 CPSE Cohort (Wave 5)**

As in previous waves, in Wave 5 statistical differences were recorded between teacher and caregiver rated school readiness and the Canadian norms. The overall pattern of teacher rated scores was similar to previous waves, with teachers in Wave 5 rating children as performing below the Canadian norm across *all domains of school readiness*. Caregivers rated children above the Canadian norm on the domains of *physical health and well-being*, *social competence*, *emotional maturity*, and *communication and general knowledge* and below the Canadian norm on the domain *language and cognitive development*. Regarding teacher and caregiver rating comparisons, caregivers rated children significantly higher than did teachers on all five domains of school readiness. Based on the teacher reports, 55% of children performed above the norm on the *social competence* domain and more than 35% scored above the norm on the *physical health and well-being*, *emotional maturity* and *communication and general knowledge* domains. Finally, 19% of children in Wave 5 scored above the norm on the *language and cognitive development* domain according to teacher ratings.

#### **V. Comparison of School Readiness in Waves 1 to 5**

Overall, the pattern of results is very similar for the five waves of data collection. In all surveys, the average caregiver rating of school readiness was higher than the average teacher rating across all school readiness domains. The difference was significant for all domains apart from *language and cognitive development* in Waves 1, 2 and 4 and *emotional maturity* in Wave 3. Two domains demonstrated significant teacher rated differences between waves of data collection. Specifically, teachers rated children in Wave 4 higher on the *social competence* domain than children in previous waves. Teachers also rated children in Wave 1 lower on *emotional maturity* domain than children in subsequent waves. In terms of caregiver ratings, significant wave differences were present on the *emotional maturity* domain. Specifically, caregivers indicated that children in Wave 3 demonstrated lower levels of *emotional maturity* than children in Waves 1, 2, 4 or 5.

Differences between the five waves in terms of *physical health and well-being*, *social competence*, and *communication and general knowledge* did not reach significance.

There was considerable variation between waves in terms of the percentage of children scoring above and below the Canadian norm. The percentage of children scoring above the Canadian norm on the *physical health and well-being* domain across all waves has remained largely constant. In addition, a higher percentage of children in Waves 2 and 4 scored above the norm on the *social competence* and *communication and general knowledge* domains compared to Wave 1. However the percentage of children across Waves 1, 3 and 5 scoring above the norm on these two domains has increased steadily, suggesting a small consistent improvement over time in children's school readiness skills. In terms of *emotional maturity*, the percentage of children performing above the norm increased from Wave 1 to Wave 2 and remained at a similar level in Waves 3 and 4, and subsequently decreased in Wave 5. Finally, the percentage of children scored above the norm on the *language and cognitive development* domain appears to be declining over time, with scores showing a consistent reduction over Waves 3, 4 and 5.

There was a decrease in the percentage of children scoring in the lowest 10% on any one domain, from Wave 1 to Wave 4, suggesting that fewer children in Waves 2, 3 and 4 were performing in the lowest 10% of the Irish cohort on any domain of school readiness. However Wave 5 data were similar to Wave 1. In Wave 5, 64.86% of children did not score in the lowest 10% on any domain. There were fewer children vulnerable on two domains in Wave 5 than Wave 4, suggesting an increase in school readiness for some children. However, across the 5 waves no discernible pattern emerged.

### ***1. Discussion of Wave Differences in School Readiness***

There are several possible explanations for these findings. First, as different teachers have participated throughout this survey, it is possible that the teachers may have a different frame of reference on which to base their assessments. Additionally, as some of the teachers in Waves 3, 4 and 5 participated in previous waves, it is possible that their frame of reference has evolved with the additional years of teaching experience. Second, these results may represent a cohort effect such that the children in each wave display different levels of school readiness. Third, the *PFL*

programme may be generating externalities as it is possible that some of the Junior Infant children may have younger siblings, family members, or neighbours participating in the *PFL* programme. However, only 46 (8.1%) of children in the entire CPSE cohort are in families participating in the *PFL* programme. Therefore, it is unlikely that positive externalities are being transmitted at the family level, and thus we are experiencing little improvement in skills over time.

## **W. Discussion of Differences in Teacher and Caregiver Reported School Readiness**

An important observation of this report is that several differences emerged between teacher and caregiver reports on the S-EDI across all waves of data collection. Such discrepancies across informants have been documented elsewhere and are a common finding in the literature (e.g., Gagnon, Vitaro, & Tremblay, 1992; Shaw, Hammer, & Leland, 1991; Tasse & Lecavalier, 2000). Additionally, teachers and caregivers often have different definitions of school readiness, which may affect the school readiness ratings in the CPSE survey. A clear pattern emerged from the importance ratings such that teachers place more importance on non-cognitive skills, while caregivers appear to place a greater emphasis on being physically ready for the school day. This is in line with research indicating that teacher definitions of school readiness focus more on non-academic skills compared to parent ratings of school readiness, which focus more on academic skills (Knudsen-Lindauer & Harris, 1989; West, Hausken, & Collins, 1993). For example, parents rate knowledge of the alphabet and ability to count as essential components of school readiness however, both items are rated as very low in importance by teachers (Lewit & Baker, 1995). Additionally, teachers are more likely to rate the child's ability not to disrupt a class high on importance for school readiness (Harradine & Clifford, 1996).

There are several possible explanations for the observed discrepancies in the current report. First, caregivers may perceive the same child behaviours differently to teachers. Teachers observe multiple children daily and over many years, whereas caregivers may only regularly observe their own children, children in their community, or neighbours' and friends' children. Additionally, while teachers may interact with children from a range of areas, communities and cultures, caregivers may only be familiar with the children living in their own area. Therefore,

the frame of reference upon which assessments of child skill and behaviour are made may differ for teachers and caregivers. In relation to frame of reference as an explanation for reported discrepancies, it is worth noting that this study was conducted in a disadvantaged area with above national levels of unemployment and social welfare dependency (Census Small Area Population Statistics, 2006). The frame of reference upon which the caregivers are rating their children may be skewed, with caregivers considering their children as performing above average for the community. This might be viewed as a downward social comparison (Wills, 1981) as caregivers witnessing low levels of school readiness in the community may perceive their children as displaying higher levels of school readiness relative to other children living in the area. In contrast, teachers may rate children's behaviours in comparison to a larger pool of children from multiple areas, including those living in more advantaged communities demonstrating higher levels of school readiness. Therefore, teacher ratings may be influenced by their experience of interacting with children at different ends of the social spectrum.

Secondly, the discrepancy between teacher and caregiver reported school readiness may be a function of children exhibiting different behaviours in a school context than in a family context. Children's behaviours, whether problematic or not, have long been conceptualised as responses to different social situations (Mischel, 1968), and therefore, caregivers and teachers may be rating different behaviours. For example, children may be expected to follow different rules in the school and home environments, and the consequences for their actions may differ across contexts. Thus, children may learn that behaviours which are acceptable at school may not be acceptable at home, and vice-versa, resulting in different behaviours being exhibited in different environments. This is commonly referred to as the situational specificity hypothesis and has been supported by several research findings. For example, child behaviour has been shown to cluster between school and home settings, and even when antisocial behaviour is found in both situations, the type of behaviour differs across settings (Wahler, 1975). Young children's behaviour also may vary according to the type of situation they are in, and depend on the constraints placed upon them, for example in a teaching versus a playtime situation (Rose, Blank, & Spalter, 1975). It is therefore possible that caregivers and teachers may be providing accurate reports of the behaviours that they witness. However, further research is required to

understand the situational specificity of other, non-behavioural skills encompassed in school readiness, such as language, literacy, and physical well-being.

In addition, these divergences may represent differential capabilities that are focused on in the school and home environments. To examine possible reasons why these discrepancies may exist, discrepancies in the CPSE Wave 1 cohort were examined as a function of child's gender, teacher experience, and caregiver education. In this analysis, differences in teacher and caregiver reported S-EDI school readiness domains remained (Doyle, Finnegan, & McNamara, 2010), suggesting that these factors cannot explain the differences in teacher and caregiver reports.

Although the lack of concordance between teacher and caregiver ratings of children's school readiness may be viewed simply as a methodological problem, it may represent a more interesting finding. Specifically, parents in disadvantaged areas may view their children as thriving in the environment and therefore they may not recognise any weaknesses in their children's school readiness, and subsequently they may not recognise the need for early intervention. Furthermore, these results cannot definitively show whether the discrepancies in teacher and caregiver reports of child's school readiness are simply due to a response bias in terms of the teachers or caregivers, or whether the difference is due to context specific behaviour on the part of the children. Understanding why these differences exist is important as being exposed to diverging messages about the skills important for school success may lead to lower levels of school readiness for young children.

#### **X. Subjective Ratings and Importance of School Readiness Domains**

Teachers in the 2012-2013 CPSE (Wave 5) cohort indicated that 55% of children were *definitely ready* for school when they started in September, 2012, compared with 56% of children in the 2011-2012 (Wave 4) cohort, 52% in the 2010-2011 (Wave 3) cohort and 48% in the 2009-2010 (Wave 2) cohort. As these figures are broadly in line with the 48% of children reported as being *definitely ready* for school in September, 2004, it suggests that there have been few improvements in children's school readiness, as reported by teachers, in the *PFL* communities over an eight year period.

## **Y. Factors Associated with School Readiness**

In addition to measuring the level of school readiness in the *PFL* catchment area, the report also investigated how school readiness differed by socio-demographic, health, and environmental factors. The report replicated several of the findings from the 2004 school readiness survey conducted in the *PFL* catchment area (Kiernan et al., 2008). All significant differences were identified with moderate effects sizes. Older children were reported as being more ready for school, with differences in the social competence, physical health and well-being, and language and cognitive development domains, however only differences in social competence remained significant when other relevant factors were controlled for. In addition, girls were more ready for school across all five domains of school readiness than boys, however, only differences in the social competence, emotional maturity, an communication and general knowledge domains remained significant when relevant socio-demographic, health, and environmental factors were held constant. Several group differences in school readiness also were identified between high and low resource families, with children from high resource families typically performing above those from low resource families. Specifically, children of parents with less than a Junior Certificate qualification were not as ready for school as their classmates, a finding supported in the literature (Janus & Duku, 2007). While many of the significant SES relationships identified in the bivariate analyses no longer remained in the multivariate analysis, relatively low caregiver education still was associated with poorer physical health and language and cognitive development. It is important to note that a lack of resources may play a direct role in school readiness. For example, parents of children who are less ready for school may not possess the necessary financial, material, and social resources to help prepare their children for school.

Another interesting finding emerged in regards the relationship between the presence of siblings and child school readiness. Children with no siblings were rated as being more physically healthy, more socially competent, and displaying higher levels of language and cognitive development and communication and general knowledge. Additionally, an examination of the total number of siblings present in the household demonstrated that not only does the presence of siblings matter for a child's school readiness, so too does the number of siblings living in the household. However, none of the relationships remained significant when relevant socio-demographic, health, and environmental factors were controlled for in the multivariate analysis.

There are several plausible explanations for this unexpected finding. First, children without any siblings living in the same house may be modelling their behaviour after their parents, rather than siblings; and parents of only children may be better equipped to provide the necessary resources required for a child to be physically ready for the school day.

The significant relationships observed between parenting behaviours and certain dimensions of school readiness are generally in accordance with the literature. In the present report, authoritarian parenting behaviours were associated with lower levels of school readiness, which is consistent with literature identifying associations between authoritarian parenting and children's problematic peer interactions, lower peer acceptance and greater incidence of externalising behaviour problems (Baumrind, 1967; Brenner & Fox, 1998; Kahen, Katz, & Gottman, 1994; Stormshak, Bierman, McMahon, & Lengua, 2000). Additionally, permissive parenting was negatively associated with school readiness, which replicates findings by Querido, Warner, and Eyberg (2002) and Williams et al. (2009). This may be associated with caregiver laxness in monitoring or managing the eating habits and physical activities of their children (Birch & Fisher, 1998; Davison & Birch, 2001).

### **Z. Caregiver Health & School Readiness**

The second, third, fourth and fifth waves of CPSE data collection addressed the mental well-being and self-reported health of caregivers. Additionally, depressive symptomology was assessed in Wave 3, Wave 4 and Wave 5. Overall, the caregivers in the *PFL* communities report quite positive health. While 72% of caregivers reported having excellent or very good general health, 72% reported their mental well-being as being above the threshold for being classified as having poor mental health, and 82% reported low depressive symptomology. While many studies report that children of mothers who are suffering from depression or poor mental health often score lower on tests of school readiness (Barry, Dunlap, Cotton, Lochman, & Wells, 2005; Lesesne, Visser, & White, 2003; Linver, Brooks-Gunn, & Kohen, 2002), no significant relationship was found between the S-EDI domains and the mental well-being of caregivers. However, significant relationships were present between depressive symptomology and the social competence, emotional maturity and language and cognitive development domains, with

children of caregivers who reported lower symptomology displaying higher levels of school readiness. Additionally, several strong effects were present in the relationship between subjective health of the caregiver and the school readiness of the child. There were statistically significant relationships, at least at the trend level, between subjective health and three of the five domains of school readiness. Specifically, strong associations were present between caregiver subjective health and the child's *physical health and well-being*, *social competence* and *communication and general knowledge* indicating that children of caregivers who report better health are more ready for school. However, none of these results remained in the multivariate analysis controlling for all characteristics. The bivariate result is in line with other studies which report strong relationships between maternal health and child development (Janus & Duku, 2007; Johnson, Swank, Baldwin, & McCormick, 1999; Kahn, Zuckerman, Bauchner, Homer, & Wise, 2002). This is an important finding, especially in disadvantaged areas where individuals may be at increased risk for poor health.

#### **AA. Centre-based Childcare & School Readiness**

As formal childcare has been identified as one of the key promoters of early school readiness (National Institute of Child Health and Human Development Early Childcare Research Network, 2000; 2002), the CPSE survey collected information about the children's childcare experiences prior to school entry in terms of childcare type, duration, and starting age. A significant finding of this report is that the majority of children in the cohort had experienced some form of centre-based childcare prior to starting school. The results also indicate that children experienced informal childcare (e.g., care by grandparents, other relatives or nannies) for an average of 30 months and formal childcare (e.g., care in nursery or Montessori school) for 20 months. Studies typically find that children from disadvantaged areas are more likely to avail of informal, rather than formal, childcare (Petitclerc et al., 2011), however, this result is not borne out in the CPSE cohort.

Several significant relationships were identified between participation in centre-based childcare and school readiness. Children who participated in centre-based childcare were rated higher than children who did not attend centre-based childcare on the domains of language and cognitive

development and communication and general knowledge. However this relationship did not reach significance when relevant socio-demographic, caregiver, and environmental factors were held constant in the multivariate analysis. These findings are consistent with the literature which suggests that centre-based childcare is beneficial for children's development (National Institute of Child Health and Human Development Early Childcare Research Network, 2000; 2002). There also is established evidence that the benefits of childcare may be greatest for those from disadvantaged backgrounds as childcare can play a protective role for children from low resource families (Geoffroy et al., 2006; Caughy, DiPietro, & Strobino, 1994), especially in terms of physical aggression (Borge, Rutter, Côté, & Tremblay, 2004) and emotional maturity (Côté, Borge, Geoffroy, Rutter, & Tremblay, 2008).

Furthermore, studies consistently show that the quality of childcare matters (Burchinal et al., 2000), particularly in terms of the qualification of childcare staff, the stability of staff, and the structure and content of daily activities. However, this study does not control for the quality of the childcare settings which the CPSE cohort attended. Síolta, the National Quality Framework for Early Childhood Education, which provides the first nationally agreed set of standards for early childhood care and education in Ireland, is currently being implemented by the local preschools, schools, and childcare settings in the *PFL* catchment area as part of the *Preparing for Life* programme. This framework aims to raise the standards of the childcare settings within the *PFL* community, therefore a separate paper which incorporates these measures to analyse the effects on school readiness over time will be prepared.

## **BB. Conclusion of Findings**

This report serves as an update for an on-going assessment of the school readiness of children living in the *PFL* catchment area. Overall, there is little improvement in the level of school readiness in the community based on multiple forms of assessment. However, as the sample size increases, it is possible to identify several relationships from the data. Interestingly, many significant relationships emerged between school readiness and child characteristics, such as age and gender, and environmental characteristics, such as participation in centre-based childcare. Familial factors, such as presence of siblings and dependence on social welfare, were associated with various domains of school readiness, while caregiver characteristics show mixed results.

Specifically, caregiver age and mental well-being were not associated with any domains of school readiness, but education, employment status, depressive symptomology, and subjective health displayed significant relationships with at least some domains of school readiness. Furthermore, with the expansion of the sample across waves the patterns of relationships appear to be more established. Collectively, the results of this study illustrate the complexity of the factors associated with school readiness.

### **CC. Strengths and Limitations of the Study**

The present study has several strengths. First, the reliability of the scales used in the analyses was acceptable, with the reliability of several scales falling above the .80 level. Additionally, the response rates of teachers and caregivers were high for a study of this type. Another clear strength of the study is that non-standard statistical methods were employed, specifically tailored to accommodate and maximise the sample size used in the analyses. Another benefit of the study is the holistic approach to school readiness through which this survey was designed. Lastly, although the results reported here focused on teacher reported school readiness, data also were obtained for caregiver reports of school readiness. By obtaining both teacher and caregiver reports of school readiness, important differences in these ratings were elucidated which has several implications for future work in this area.

There also are several limitations to the study that should be noted. Firstly, all the analyses conducted to test for differences in school readiness across the range of socio-demographic, health, and environmental factors represent correlations or associations in the data. They are indicative of underlying relationships that may exist between two factors, however, they are not necessarily causal relationships, nor should they be interpreted as such. Secondly, this is one study conducted in a disadvantaged area of Ireland and therefore cannot be generalised to the larger population.

### **DD. The Need for the *PFL* Intervention**

The CPSE survey was conducted as part of an overall evaluation of the *PFL* early childhood intervention programme. It is clear, based on teacher assessments of school readiness, that children in the *PFL* catchment area are not performing to the level of other children at school entry, a finding that provides quantitative evidence for the need of the *PFL* intervention.

Additionally, the vast differences between teacher and caregiver assessments of school readiness provide solid evidence that any intervention aiming to improve levels of school readiness in this area must integrate several contexts of development rather than simply focusing on one context.

#### **EE. Future CPSE Surveys**

The current report provides a comprehensive analysis of the levels of school readiness of Junior Infant children in a disadvantaged urban community in Ireland. The survey will be replicated and conducted annually until the end of the PFL evaluation. One of the aims of this study is to measure the general level of school readiness in the area for the cohort of children who are not receiving the *PFL* programme. By comparing the year-on-year changes in school readiness, this study will indicate if the *PFL* programme is generating positive externalities. It will determine whether providing an intensive school readiness intervention to the community's younger cohort will have knock-on effects for the older children in the community starting school between 2008 and 2015. Additionally, the combined CPSE surveys will serve as a baseline measure of school readiness for children receiving the *PFL* early childhood intervention. The current report elucidates several interesting relationships in the data in terms of factors influencing school readiness. Continuing to combine the samples of future CPSE surveys over time will provide more data which may deepen the richness of the analysis and allow researchers to fully investigate the determinants and antecedents of school readiness of children living in disadvantaged areas in Ireland.

## Appendix A: Instruments: Example Items

Table 1  
*Domains, Subdomains, and Example Items for the Parenting Styles and Dimensions Questionnaire*

Domain	Number of Items	Example Items
<b>Authoritative Parenting</b>		
<i>Connection</i>	5	Encourages child to talk about the child's troubles; gives praise when child is good
<i>Regulation</i>	5	Explains the consequences of the child's behaviour; emphasizes the reasons for rules
<i>Autonomy</i>	5	Shows respect for child's opinions by encouraging child to express them; allows child to give input to family rules
<b>Authoritarian Parenting</b>		
<i>Physical Coercion</i>	4	Spanks child when disobedient; uses physical punishment as a way of disciplining child
<i>Verbal Hostility</i>	4	Explodes in anger toward child; scolds and criticises to make child improve
<i>Non-Reasoning/Punitive Behaviours</i>	4	Punishes by taking privileges away from child with little if any explanations; uses threats as punishment with little or no justification
<b>Permissive Parenting</b>		
<i>Permissive</i>	5	States punishments to child and does not actually do them; spoils child

Table 2  
*Domains, Subdomains, and Example Items for the S-EDI*

Domain	Number of Items	Example Items
<b>Physical Health &amp; Well-being</b>		
<i>Physical Readiness for the School Day</i>	3	Over/underdressed for school related activities; too tired/sick to do schoolwork
<i>Physical Independence</i>	3	Independent in washroom habits most of the time; well coordinated
<i>Gross and Fine Motor Skills</i>	3	Ability to manipulate objects; overall physical development
<b>Social Competence</b>		
<i>Respect and Responsibility</i>	3	Respects the property of others; accepts responsibility for actions
<i>Approaches to Learning</i>	3	Works independently; able to follow class routines without reminders
<i>Readiness to Explore New Things</i>	3	Eager to play with a new toy; eager to play with/read a new book
<i>Overall Social Competence with Peers</i>	3	Ability to get along with peers; plays and works cooperatively with peers at age appropriate level
<b>Emotional Maturity</b>		
<i>Prosocial and Helping Behaviour</i>	3	Will try to help someone who has been hurt; comforts a child who is crying or upset
<i>Aggressive Behaviour</i>	3	Gets into physical fights; bullies or is mean to others
<i>Anxious and Fearful Behaviour</i>	3	Appears fearful or anxious; appears worried
<i>Hyperactive and Inattentive Behaviour</i>	3	Can't sit still; is restless or fidgets
<b>Language &amp; Cognitive Development</b>		
<i>Basic Literacy Skills</i>	3	Is able to attach sounds to letters; is able to identify at least 10 letters of the alphabet
<i>Advanced Literacy Skills</i>	3	Is able to read simple words; is able to read simple sentences
<i>Basic Numeracy Skills</i>	3	Is able to count to 20; is able to say which is the bigger of the two
<i>Interest in Literacy/Numeracy and Memory</i>	3	Is interested in reading; is interested in games involving numbers
<b>Communication &amp; General Knowledge</b>		
<i>Communication &amp; General Knowledge</i>	3	Is able to tell a story; is able to communicate in an understanding way

## Appendix C: Monte Carlo Permutation Test Results<sup>15,16</sup>

Table 1

*Monte Carlo Permutation Test Results for Differences in Teacher Reported School Readiness Based on Child Gender*

Domain	Male		Female		<i>p</i>	<i>d</i>
	<i>n</i>	Mean ( <i>SD</i> )	<i>n</i>	Mean ( <i>SD</i> )		
<i>Physical Health &amp; Well-being</i>	290	7.46 (2.12)	260	8.07 (2.00)	<.001	.30
Gross and Fine Motor Skills	280	6.01 (3.11)	251	7.19 (2.78)	< .001	.40
<i>Social Competence</i>	290	7.22 (2.12)	260	7.94 (1.91)	< .01	.36
Overall Social Competence with Peers	290	5.91 (3.01)	261	6.83 (2.88)	< .01	.31
Responsibility and Respect	290	7.66 (2.59)	261	8.14 (2.41)	< .10	.19
Approaches to Learning	290	7.16 (2.67)	261	8.19 (2.32)	< .001	.41
Readiness to Explore New Things	278	8.17 (2.17)	249	8.65 (1.85)	< .05	.24
<i>Emotional Maturity</i>	285	6.49 (2.09)	259	7.57 (1.85)	< .001	.55
Prosocial and Helping Behaviour	247	4.56 (3.23)	238	6.47 (3.06)	< .001	.61
Aggressive Behaviour	282	1.96 (2.85)	258	1.20 (2.14)	< .01	.30
Anxious and Fearful Behaviour	290	4.53 (3.68)	261	3.21 (3.29)	< .001	.38
Hyperactivity and Inattention	286	2.40 (2.70)	257	1.78 (2.52)	< .05	.24
<i>Language &amp; Cognitive Development</i>	279	5.42 (2.74)	244	5.98 (2.58)	< .05	.21
Basic Literacy Skills	286	6.34 (3.59)	257	7.00 (3.52)	< .10	.19
Interest in Literacy/Numeracy/Memory	286	8.30 (3.20)	252	9.10 (2.37)	< .01	.28
Basic Numeracy Skills	287	2.10 (2.81)	256	2.67 (2.82)	< .01	.20
<i>Communication &amp; General Knowledge</i>	289	5.09 (3.60)	260	6.38 (3.27)	< .001	.37

*Note.* *n* represents the number of observations, Mean illustrates the average score, *SD* represents the standard deviation, *p* illustrates the *p*-value, and *d* corresponds to Cohen's *d* effect size. ns = not significant.

<sup>15</sup> The *p*-values represent the probability that the result obtained is due to chance rather than a true relationship between variables. Consistent with the literature, *p*-values below 0.05 (5%) are considered to be statistically significant in the present report. A *p*-value of less than 0.05 (5%), 0.01 (1%), 0.001 (0.01%) conveys that the probability that the difference between the two groups is due to chance is less than 5%, 1% and 0.01% respectively. Trend level results were reported if the *p*-value was equal to or less than .10.

<sup>16</sup> The following rule can be applied to interpreting effect sizes (Gravetter & Wallnau, 2004). A Cohen's *d* ranging from 0.0 to 0.2 is deemed a small effect (mean difference is less than .2 standard deviation), values ranging from 0.2 to 0.8 are considered to represent a medium effect (mean difference around .5 standard deviation), and values greater than 0.8 illustrate a large effect (mean difference greater than .8 standard deviation).

Table 2

*Monte Carlo Permutation Test Results for Differences in Teacher Reported School Readiness Based on Presence of Siblings Living in the House*

<i>Social Competence</i>	130	7.54 (1.99)	303	7.65 (2.09)	ns	.05
Overall Social Competence with Peers	130	6.42 (2.96)	304	6.52 (2.93)	ns	.03
Responsibility and Respect	130	7.88 (2.57)	304	8.0 (2.47)	ns	.05
Approaches to Learning	130	7.62 (2.55)	304	7.68 (2.58)	ns	.03
Readiness to Explore New Things	119	8.31 (1.96)	293	8.40 (2.09)	ns	.05
<i>Emotional Maturity</i>	127	7.09 (2.04)	303	7.17 (2.03)	ns	.04
Prosocial and Helping Behaviour	121	5.48 (3.32)	272	5.49 (3.37)	ns	.00
Aggressive Behaviour	129	1.55 (2.54)	303	1.50 (2.48)	ns	.02
Anxious and Fearful Behaviour	130	3.81 (3.75)	304	3.55 (3.40)	ns	.07
Hyperactivity and Inattention	128	1.97 (2.44)	299	1.91 (2.58)	ns	.02
<i>Language &amp; Cognitive Development</i>	124	5.81 (2.55)	292	5.76 (2.64)	ns	.02
Basic Literacy Skills	127	6.73 (3.45)	303	6.75 (3.57)	ns	.00
Interest in Literacy/Numeracy/Memory	128	8.85 (2.84)	297	8.83 (2.63)	ns	.01
Basic Numeracy Skills	129	2.30 (2.72)	300	2.39 (2.81)	ns	.03
<i>Communication &amp; General Knowledge</i>	129	5.81 (3.53)	303	5.87 (3.48)	ns	.02

*Note.* *n* represents the number of observations, Mean illustrates the average score, *SD* represents the standard deviation, *p* illustrates the *p*-value, and *d* corresponds to Cohen's *d* effect size. ns = not significant.

Table 9  
*Monte Carlo Permutation Test Results for Differences in Teacher Reported School Readiness Based on Caregiver Depressive Symptomology as Measured by the CES-D*

Domain	High Symptomology		Low Symptomology		<i>p</i>	<i>d</i>
	<i>n</i>	Mean ( <i>SD</i> )	<i>n</i>	Mean ( <i>SD</i> )		
<i>Physical Health &amp; Well-being</i>	59	7.37 (2.44)	253	7.87 (1.95)	ns	.24
Gross and Fine Motor Skills	57	6.04 (3.22)	252	6.73 (2.92)	ns	.23
<i>Social Competence</i>	60	7.07 (2.02)	252	7.72 (2.0)	<.05	.32
Overall Social Competence with Peers	60	5.81 (3.06)	253	6.55 (2.97)	ns	.25
Responsibility and Respect	60	7.70 (2.68)	253	7.95 (2.44)	ns	.10
Approaches to Learning	60	7.14 (2.44)	253	7.83 (2.36)	<.10	.29
Readiness to Explore New Things	54	7.79 (2.23)	245	8.61 (1.85)	<.05	.42
<i>Emotional Maturity</i>	56	6.59 (2.36)	253	7.22 (1.98)	ns	.31
Prosocial and Helping Behaviour	50	5.37 (3.32)	227	5.65 (3.44)	ns	.08
Aggressive Behaviour	59	1.77 (2.79)	252	1.66 (2.56)	ns	.04
Anxious and Fearful Behaviour	60	4.56 (3.88)	253	3.58 (3.41)	ns	.28
Hyperactivity and Inattention	56	2.75 (2.54)	250	1.67 (2.48)	<.05	.44
<i>Language &amp; Cognitive Development</i>	57	5.36 (2.73)	244	5.86 (2.58)	ns	.19
Basic Literacy Skills	60	6.25 (3.63)	252	6.90 (3.52)	ns	.18
Interest in Literacy/Numeracy/Memory	57	8.54 (3.33)	248	8.96 (2.49)	ns	.16
Basic Numeracy Skills	58	1.90 (2.80)	251	2.16 (2.74)	ns	.10
<i>Communication &amp; General Knowledge</i>	58	5.17 (3.66)	253	5.90 (3.47)	ns	.21

*Note.* *n* represents the number of observations, Mean illustrates the average score, *SD* represents the standard deviation, *p* illustrates the *p*-value, and *d* corresponds to Cohen's *d* effect size. ns = not significant.

Table 10  
*Monte Carlo Permutation Test Results for Differences in Teacher Reported School Readiness Based on Caregiver Subjective Well-being*

Domain	Good or Fair Health		Excellent or Very Good Health		<i>p</i>	<i>d</i>
	<i>n</i>	Mean ( <i>SD</i> )	<i>n</i>	Mean ( <i>SD</i> )		
<i>Physical Health &amp; Well-being</i>	122	7.24 (2.43)	306	8.03 (1.85)	<.05	.39
Gross and Fine Motor Skills	121	5.73 (3.19)	304	6.97 (2.84)	<.01	.42
<i>Social Competence</i>	122	7.10 (2.29)	306	7.81 (1.92)	<.05	.35
Overall Social Competence with Peers	122	6.0 (3.05)	307	6.70 (2.85)	<.10	.24
Responsibility and Respect	122	7.59 (2.77)	307	8.10 (2.38)	ns	.21
Approaches to Learning	122	6.89 (2.99)	307	7.96 (2.32)	<.01	.43
Readiness to Explore New Things	116	7.97 (2.10)	292	8.55 (2.0)	<.05	.29
<i>Emotional Maturity</i>	120	6.72 (2.35)	305	7.28 (1.88)	<.10	.28
Prosocial and Helping Behaviour	111	5.17 (3.47)	278	5.57 (3.27)	ns	.12
Aggressive Behaviour	121	1.82 (2.84)	306	1.36 (2.30)	ns	.19
Anxious and Fearful Behaviour	122	4.39 (3.82)	307	3.36 (3.32)	<.05	.30
Hyperactivity and Inattention	118	2.13 (2.49)	304	1.92 (2.61)	ns	.08
<i>Language &amp; Cognitive Development</i>	118	5.39 (2.72)	293	5.93 (2.57)	ns	.21
Basic Literacy Skills	120	6.35 (3.71)	305	6.89 (3.46)	ns	.15
Interest in Literacy/Numeracy/Memory	117	8.59 (3.01)	302	8.96 (2.52)	ns	.14
Basic Numeracy Skills	122	1.90 (2.51)	302	2.59 (2.86)	<.10	.25
<i>Communication &amp; General Knowledge</i>	121	5.08 (3.55)	306	6.18 (3.42)	<.05	.32

*Note.* *n* represents the number of observations, Mean illustrates the average score, *SD* represents the standard deviation, *p* illustrates the *p*-value, and *d* corresponds to Cohen's *d* effect size. ns = not significant

Table 11  
*Monte Carlo Permutation Test Results for Differences in Teacher Reported School Readiness Based on Participation in Centre-based Childcare*

Domain	Centre-based Care		No Centre-based Care		<i>p</i>	<i>d</i>
	<i>n</i>	Mean ( <i>SD</i> )	<i>n</i>	Mean ( <i>SD</i> )		
<i>Physical Health &amp; Well-being</i>	437	7.86 (2.04)	113	7.33 (2.20)	ns	.26
Gross and Fine Motor Skills	422	6.77 (3.03)	109	5.76 (2.83)	<.05	.34
<i>Social Competence</i>	438	7.68 (2.0)	112	7.10 (2.21)	<.10	.28
